An Examination at the University of Oxford for a *adcliffe Travelling Fellowship* (annual value £300, tenable or two years) will begin on Feb. 14th. Candidates must have assed all the examinations required for the degrees of .A. and B.M., and not more than four years must have lapsed since they passed the last examination. Intending andidates should communicate with the Regius Professor f Medicine, at the University Museum, before Feb. 1st.

The *George Herbert Hunt Travelling Scholarship* is awarded ithout examination every second year to a graduate in edicine of the University (of either sex) who has not xceeded five years from the date of passing the final xamination for the B.M. degree. The successful candidate required to travel abroad for not less than three months or the purpose of clinical study or research in medicine. reference is given to candidates who intend to practise s surgeons or general practitioners. The next election will e made next April, and applications should be sent to the ean of the School of Medicine, at the University Museum, efore Feb. 14th.

UNIVERSITY OF LONDON.—At recent examinations he following candidates were successful:—

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

With Special Knowledge of Psychiatry.—Frederick Back, J. N. Jacobson, J. M. Mackenzie, J. J. O'Reilly, and Morris Robinson, M.B., B.S.

With Special Knowledge of Mental Deficiency.—E. C. T. Emerson.

SOCIETY OF APOTHECARIES OF LONDON.—At recent xaminations the following candidates were successful:—

Surgery.—E. E. Bowen, Middlesex Hosp.; W. B. Hallums and H. T. Ince, St. Mary's Hosp.; M. H. Rashwan, Guy's Hosp.; H. T. Rylance, Middlesex Hosp.; M. E. Tscheuschner, Berlin and Charing Cross Hosp.; T. de L. Walker, King's College Hosp.; and R. W. Wood, St. Bart.'s Hosp.

Medicine.—A. F. J. D'Arcy and P. F. Fanaken, St. Mary's Hosp.; T. M. Joseph, London Hosp.; I. O. B. Shirley, St. Thomas's Hosp.; and M. E. Tscheuschner, Berlin and Charing Cross Hosp.

Forensic Medicine.—A. F. J. D'Arcy and P. F. Fanaken, St. Mary's Hosp.; L. W. Sanders, Manchester; M. E. Tscheuschner, Berlin and Charing Cross Hosp.; and J. L. M. Wood, Sheffield.

Midwifery.—J. S. Bury, Manchester; G. N. Fox, St. Bart.'s Hosp.; A. Hamid, Middlesex Hosp.; T. M. Joseph, London Hosp.; A. K. Rama Chandra, Edinburgh; and M. E. Tscheuschner, Berlin and Charing Cross Hosp.

The Diploma of the Society was granted to the following ndidates, entitling them to practise medicine, surgery, and idwifery: A. F. J. D'Arcy, P. F. Fanaken, T. M. Joseph, . E. Tscheuschner, and T. de L. Walker.

DONATIONS AND BEQUESTS.—The Royal Manchester ildren's Hospital during the past month has received gacies and donations amounting to £3498, including 000 from Mrs. G. M. Goodbehere, £900 from the late artha Jane Guest, and £500 each from the Ancient Order Frothblowers and Messrs. Peel and Co., Ltd.—Lord ble of Ideford, Calcutta, Bishops Teignmouth, Devon, and osvenor-square, W., merchant, left, besides many other quests, over £60,000 to charities, including £22,450 to the lcutta General Hospital.—Mr. Joseph Cuthbert, Sheffield d Bridlington, on the death of his wife, gives £500 each to effield Royal Infirmary, the Sheffield Royal Hospital, the effield Children's Hospital, the Jessop Hospital for omen, St. Anne's Convalescent Home, Bridlington, Lloyd's ospital, Bridlington, and the Sheffield Blind Institution.—ackburn Royal Infirmary has received £2000 under the ll of Mrs. Stewart, late of Lynwood-road, Blackburn, to dow two cots.—Mr. C. F. Edwards, of Highfield, Lathom, t £10,000 to charities including £1000 to the Ormskirk ttage Hospital and Dispensary.—Miss Violet Wells, of aytor, Devon, has given a second donation of £1000 to e new Crippled Children's Hospital, Exeter, just opened the Duchess of York.—Mrs. Robert Clayton, of the rrets, Rishton, has given £1000 to the Blackburn and st Lancashire Royal Infirmary to endow a bed in memory her late husband.—Mr. William George Evans, of Craven ms, Salop, retired medical practitioner, left estate of the lue of £17,672. After numerous bequests he gave the sidue of the property in equal shares to King's College ospital (his old hospital) and the Royal National Lifeboat stitution.—Mr. Ben Woodhead, Woodville, near Burton-Trent, left £1000 to the Burton-on-Trent General firmary.—Mr. A. W. Bowburn, of Northbury Booths Hall, near Knutsford, has sent a cheque of £2000 to the Knutsford Hospital for a new children's ward.—Mr. Douglas Cow, of Streatham, has sent a cheque for £1000 to the Queen Charlotte's National Mother-Saving Campaign, and has applied for 1000 of its Cradle Bonds.—The Victoria Infirmary, Northwich, has received during the present year £1000 from the Northwich and District Hospital Saturday Committee.

UNIVERSITY OF STRASBOURG.—Honorary degrees were recently conferred in person on Dr. G. H. F. Nuttall, F.R.S., Quick Professor of Biology at Cambridge, and Sir Charles Sherrington, O.M., F.R.S., Wayneflete Professor of Physiology at Oxford.

ROYAL SOCIETY OF MEDICINE.—Dr. Alice Bloomfield has been granted an extension of the William Gibson Research Scholarship for a third year. The next award of the scholarship will therefore be made in June, 1929.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—The Langley Memorial Prize, which was founded by a friend of the late Dr. W. H. Langley, principal medical officer of Southern Nigeria, has been awarded to Dr. A. S. Burgess, of Accra, Gold Coast, West Africa, for his paper the Selection of a Strain of *Bacillus pestis* for the Preparation of Vaccine, with Special Reference to the Effect of Animal Passage on Virulence.

HARVEIAN SOCIETY OF LONDON.—The awards in connexion with the Buckston Browne prize for the best essay on the Pathology, Diagnosis, and Treatment of New Growths Originating in the Walls of the Urinary Bladder are as follows: Mr. L. R. Fifield, F.R.C.S., £100 and medal, proxime accessit, Mr. M. F. Nicholls, F.R.C.S., £10. An epitome of the prize essay will be read by Mr. Fifield at the next meeting of the Society, to be held at the Town Hall, Paddington, on Thursday, Dec. 8th, at 8.30 P.M. The presentation of the medal and cheques will take place at the annual general meeting, which will be held at 8.30 P.M. on Jan. 12th, at 11, Chandos-street, W. 1.

ROYAL AIR FORCE MEDICAL SERVICE.—The annual dinner of the Royal Air Force Medical Service was held at the Connaught Rooms, London, on Friday, Nov. 25th, the Director, Air Vice-Marshal David Munro, C.B., C.I.E., being in the chair. The interesting point of the dinner was that the Chairman, in proposing the health of the guests, for whom Lieut.-General Sir Matthew Fell, the Director-General, A.M.S., responded, dealt in a frank way with the difficulties which at present exist in the recruiting of medical officers. He admitted the need for more officers, but gave reasons for believing that there were factors likely to make the shortage less acutely felt, and others which would attract a sufficient number of entrants. He emphasised especially the alteration in the proportion of officers serving overseas to those at home, due to reductions in Iraq and expansion at home; and the increase in the proportion of permanent officers due to the decision by the Warren Fisher Committee to allow a 50 per cent. chance of getting a permanent commission to all short service officers. The shortage of officers and frequent changes of personnel caused, he pointed out, embarrassments in making a selection for training young permanent officers, for the replacement later on of those engaged in various branches of professional work. The Service required good surgeons, pathologists, and physicians in its hospitals, and also experts in dealing with the medical and physiological problems peculiar to aviation, as well as ophthalmologists and otologists. At the present moment the supply was adequate, but the shortage stopped opportunities for study leave, and without study leave the necessary courses of special training could not be obtained. In connexion with officers serving at small aerodrome stations, he pointed out that these were the men who could not get leave owing to shortage, and that their work, often single-handed and without a well-equipped hospital in the background, was monotonous, even while it had to be of good quality. To meet the drawback it was intended, he said, to give better opportunities for practice to these officers by removing the bar on their retaining none but the lightest cases in sick quarters, and by encouraging a freer use of their cottage hospitals, whose equipment would be revised, while arrangements would be made for extra assistance when required. A measure of executive responsibility over the medical personnel on the station would also be granted—a most valuable way, said the speaker, of teaching officers to take general responsibility. He announced the imminent creation of new posts for wing commanders. Air Vice-Marshal Munro closed by referring to the opening of the Halton Hospital (see THE LANCET, Nov. 5th, p. 995, &c.), where the medical training for medical officers and medical airmen would inculcate Service methods in a Service atmosphere at the initial stages.

Mr. Percy James Kelly, M.B., Ch.B. Glasg. (Surgeon-General), has been appointed a member of the Executive Council of the Colony of British Guiana for a further period.

LONDON HOSPITAL.—The Bernhard Baron Institute of Pathology will be opened by Sir Humphry Rolleston on Tuesday, Dec. 6th, at 3 P.M.

A WOMEN'S POOR-LAW HOSPITAL.—A new women's hospital, erected by the Wirral, Cheshire, board of guardians, at a cost of £30,000, has been opened at Clatterbridge. The building has accommodation for 112 patients and comprises surgical and medical sections, each with a 28-bed ward, a 12-bed ward, and a large number of smaller wards.

EXPERIMENTAL FARM FOR CANCER RESEARCH.—Mr. Harold Sutcliffe and his brother, Mr. Norman Sutcliffe, have purchased the Lumley Hall estate of 21 acres and a manor house at South Milford, near Selby, and have presented it to the Yorkshire Council of the British Cancer Research Campaign, to be used as an experimental farm, for the purpose of carrying out experiments upon large animals. Dr. R. D. Passey, Director of Cancer Research in the University of Leeds, will live on the farm.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Dec. 5th, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., Dr. R. Travers Smith will speak on Practical Hints in Medicine. This lecture is free to members of the medical profession. A daily course of lecture-demonstrations in the in- or out-patient department of the West End Hospital for Nervous Diseases is now in progress. From Dec. 5th to 17th, at 2 P.M., at the Infants Hospital, there will be a course primarily for medical officers of welfare centres; visits will be paid to various centres. Between the same dates, at the Blackfriars Skin Hospital, a course will be given, including two special demonstrations of cases. In January courses will be held in medicine, surgery, and the specialties at the Prince of Wales's General Hospital; in diseases of children at the Children's Clinic; in cardiology at the National Hospital for Diseases of the Heart (entries limited to 20); and in psychological medicine at the Bethlem Royal Hospital. Information, syllabuses of special and general courses, and tickets may be had from the Secretary of the Fellowship, 1, Wimpole-street, London, W. 1.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 49 cases were considered and £676 voted to 40 applicants. The following are notes on some of the cases relieved.

Widow, aged 54, of M.R.C.S. who died suddenly this year. Left with two sons and one daughter, all of whom are training. Applicant hopes to have about £65 per annum when her husband's estate is settled. Her private income is £20 per annum, and she has a resident post at £28 per annum. Asks for help to meet second son's fees up to Christmas. Voted £35.

Widow, aged 43, of M.B. Lond. who was recently removed to a mental hospital as a free patient. Has two girls and a boy. Eldest girl at a boarding school paid for by her godmother. Boy at a boarding school and the youngest is with applicant. They are now living on the amount received from the sale of the practice and the money is nearly exhausted. The Fund is asked to help with the boy's school fees as applicant hopes to manage to meet her other expenses by sweet-making and needlework. Voted £21 10*s*.

Widow, aged 74, of M.D. Lond. who died in 1915. She has maintained herself by teaching, but owing to age and ill-health finds it difficult to continue. Her expenses are about £2 a week and her income is derived from the Freemasons (£56 per annum) and a merchants' Guild (£40). Fund voted £30 in two six-monthly instalments.

Daughter, aged 50, of M.D. St.And. who died in 1880. Was brought up by a sister and since leaving school has maintained herself. Now only able to get temporary posts. Voted £5 and asked to let the Fund know how she is getting on.

Daughter, aged 55, of L.R.C.P. Edin. who died in 1878. On her brother's marriage in 1907 was left without means and had to support herself. A relative allows her 10*s*. a week and for some time she has been living on her savings which are rapidly becoming exhausted. Some friends have given her hospitality temporarily. Voted £26 in four quarterly instalments.

Widow, aged 58, of L.R.C.P.I. who practised in Lancashire and died in 1911. She has maintained herself and daughter since the death of her husband, but owing to indifferent health is not able to do heavy work and is now only earning 10*s*. a week while the Irish Medical Benevolent has sent her £15. Voted £20.

Widow, aged 62, of M.D. Edin. who died in 1906. Left with a son and daughter. The daughter, now 29, is a dispenser at £2 10*s*. a week, but does not live at home. Son, aged 26, suffers from defective hearing and is only able to get odd work, which amounts to about 15*s*. a week; he is otherwise dependent on his mother, whose total income amounts to about £90 per annum, less rates at £10 10*s*. a year, the house belonging to applicant. Total Fund grants £30. Voted £18, a renewal of previous grant.

Subscriptions may be sent to the honorary treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—meeting will be held on Friday, Dec. 9th, at 8.45 P.M., at t Miller General Hospital, Greenwich, when Mr. Victor Bonn will deliver the Purvis Oration, his subject being Puerpe Sepsis.

NATIONAL COUNCIL FOR MENTAL HYGIENE.—Dan Mary Scharlieb and other speakers are to address a pub meeting, to be held at the College of Nursing, Henriett street, Cavendish-square, W., on Friday, Dec. 9th 4.45 P.M. Lord Southborough will preside.

SAFEGUARDING OF KEY INDUSTRIES.—The Treasu have made an order exempting the following articles fr Key Industry duty until Dec. 31st, 1928: bromural (dorn gene), eukodal, lithium carbonate, lithium hydroxide, nic hydroxide, papaverine, potassium permanganate, quini ethyl-carbonate, resorcin (resorcinol), and styracol (guaia cinnamate).

HOME OFFICE INDUSTRIAL MUSEUM.—The Hon Office Industrial Museum, Horseferry-road, Westminst will be open to the public from Monday next. It contai a permanent exhibition of methods and appliances securing the safety, health, and welfare of the workers factories and other industrial processes which come und the administration of the Home Office. The King a Queen intend to pay a private visit to the museum to-da Dec. 2nd.

INTERNATIONAL COURSE IN PUBLIC HEALTH.—T medical officers of foreign countries who are in London attend this course visited the Institute of Hygiene Nov. 29th, and, in the unavoidable absence of the Preside Sir Thomas Oliver, were received by Lieut.-Colonel R. Elliot. Members of the course have recently visited ma institutions in and around London, including the laborator of the Metropolitan Water Board, the Royal Sanita Institute, the Museum of the London School of Hygie and Tropical Medicine, the Houses of Parliament, t Maudsley Hospital, and London County Council sch treatment centres. To-morrow (Saturday) they are going see the Treloar Cripples' Home at Alton.

HAMPSTEAD GENERAL AND NORTH-WEST LONDO HOSPITAL.—A luncheon was held at the Savoy Hotel Tuesday, Nov. 29th, to launch the appeal which Mr. A. Milne is making for £20,000 for the hospital, £10,000 which is needed to pay off a debt, £5000 in annual subscri tions to ensure the required income, and £5000 to provi an additional operating theatre and eight extra casual beds to deal with the motor and other accidents broug to the hospital. Mr. H. B. Figgis, the hon. treasurer, w in the chair, and Sir William Collins, the Marquis of Campd Mr. Bransby Williams, the Bishop of Willesden, and M George Waugh (the senior surgeon) also spoke. An amusi and moving appeal from Mr. Milne was circulated, to t terms of which we hope to refer later.

ROYAL DENTAL HOSPITAL OF LONDON.—T annual dinner of the staff and past and present studer was held on Nov. 26th, at the Trocadero Restaurant, unc the chairmanship of Mr. J. S. Amoore. Among the gue were Sir William Goschen, who has just been appoint chairman of the hospital; Prof. W. H. Gilmour, Preside of the British Dental Association; Mr. L. G. Brock, of t Ministry of Health, Dr. A. W. Oxford, and the Deans of t Middlesex and King's College Hospitals. After the loyal to the Chairman proposed the health of the Past and Prese Students. Looking back, he said, what struck him most w the difference between the way in which diseases of the tee were regarded in 1880 (when he had last spoken at the annu dinner) and the present attitude towards them. T importance of dentistry was at long last beginning to da upon the public, and looking forward, he saw a time wh the needs of dental hospitals would be more fully recognis and when these institutions would not have to be large supported, as they were at present, by the profession itse Mr. H. C. Cooper replied for the past and Mr. H. L. Hill the present students, Dand the ean, Dr. Stobie, gave summary of the present position of the school. The numb of the students had dropped from 135 to 104 in the last ye but this had been anticipated some years ago, and was t normal reaction from the big influx just after the war. T entries this term, on the other hand, had been 23 as co pared with 14 in 1926. The teaching staff were tryi their best to benefit the post-graduate as well as the prese students, and to that end had taken steps to form some ki of amalgamation with the general hospitals. This amalgam tion had already taken place for social and athletic purpos with Charing Cross Hospital, and this was a step in the rig direction. Other speakers during the evening were Sir Jo Rose Bradford and Mr. W. H. Dolamore.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Dec. 6th.—8.30 P.M., ORTHOPÆDICS. Discussion on Fractures of the Spine. Opener: Mr. Geoffrey Jefferson. Other speakers: Dr. George Riddoch, Dr. Bertram Shires, Mr. George Stebbing, and Mr. St. J. D. Buxton. 8.30 P.M., PATHOLOGY. Laboratory meeting at the Laboratories of the Imperial Cancer Research Fund, 8–11, Queen-square, W.C. Papers and demonstrations: W. Cramer: An Experimental Study of Precancerous Conditions. A. M. Begg and J. A Murray: Histopathology and Histogenesis of a Filtrable Endothelium of the Fowl. J. A. Murray: Demonstration of Preparations of Lymph Nodes of the Fowl. R. J. Ludford: Microchemical Cytology (demonstration). Other papers and demonstrations.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Fleet Surgeon W. E. Home, R.N.: Francis Home, 1719–1813. Professor of Materia Medica in Edinburgh. Surgeon Rear-Admiral Sir Reginald Bankart: A Note on the "Weekly Medico-Chirurgical and Philosophical Magazine." 4 P.M., SURGERY. Meeting at St. Thomas's Hospital, S.E. 4.30 P.M., Tea in the Shepherd Memorial Hall. 4–5 P.M. In the Jenner Laboratory: Demonstration of Rapid Diagnosis of Tumours by Staining Scrapings by Prof. L. S. Dudgeon and Mr. C. V. Patrick. In the Physio-Therapeutic Dept.: Demonstrations by Drs. Timberg, J. B. Mennell, and Baucus. In the X Ray Dept.: Demonstrations by Drs. Fildes and Shires. In the North Theatre: Operations by Mr. Howarth and Mr. Romanis. 5 P.M., in the Clinical Theatre. Demonstration of selected cases by Mr. P. Sargent. Demonstration of Genito-urinary cases by Mr. C. Nitch. Demonstration of a group of cases by Sir Cuthbert Wallace. Demonstration of cases showing the results of operation for Osteoarthritis of the Hip by Mr. C. Max Page. Demonstration of Orthopædic cases by Mr. W. Rowley Bristow.

THURSDAY.—5.30 P.M., BALNEOLOGY. Samuel Hyde Memorial Lecture: Dr. Whitridge Davies: Problems and Opportunities for Research in Spa Treatment. 8.30 P.M., NEUROLOGY. Discussion on Traumatic Neurasthenia and the Litigation Neurosis, to be opened by Sir Farquhar Buzzard, followed by the Right Hon. H. P. Macmillan, Sir James Purves-Stewart, Dr. Risien Russell, Dr. W. A. Brend, and Dr. W. Salisbury Sharpe.

FRIDAY.—5 P.M., OPHTHALMOLOGY. Clinical meeting at the Royal London Ophthalmic Hospital, City-road, E.C. Tea at 4.30 P.M. Cases, including a number for slit-lamp, will be shown. A demonstration will be given of apparatus for exercising heterophoria and squint cases. 5.30 P.M., CLINICAL. (Cases at 5 P.M.) Cases: Dr. George Rossdale: (1) A Case of Still's Disease Cured by Intercurrent Diphtheria. Dr. Donald Hunter: (2) A Case of Co-arctation of the Aorta. Dr. D. Evan Bedford: (3) A Case of Primary Sclerosis of the Pulmonary Artery; (4) Aneurysmal Dilatation of the Pulmonary Artery in a Case of Congenital Heart Disease. Mr. Cecil P. G. Wakeley: A Case of Lymphangioma of the Tongue.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, Dec. 8th.—A meeting will be held at 11, Chandos-street, Cavendish-square, preceded at 7.45 P.M. by a demonstration illustrating the subject of the lecture. The chair will be taken at 8.15 P.M. and Dr. William Fletcher will give an address, illustrated by lantern slides, on Recent Work on Some Malayan Fevers.

BIOCHEMICAL SOCIETY.

FRIDAY, Dec. 9th.—4.45 P.M. (in the Imperial College of Science Metallurgy Theatre, Royal School of Mines, Prince Consort-road, South Kensington). Communications: H. Henderson Smith, M. Hume, and I. Smedley MacLean: On the Presence of Vitamin A and Provitamin D in Yeast Fat. W. T. J. Morgan and R. Robison: Dephosphorylated Methylhexosides Derived from Hexosediphosphoric Acid. J. Pryde and E. T. Waters: Organic Phosphates from Rabbit's Muscle. H. R. Hewer, H. Jairam, and S. B. Schryver: The Chemical Changes Taking Place in the Proteins of Muscular Tissue when Passing into Rigor. H. J. Holman and S. B. Schryver: The Basic Hydrolysis Products of Certain Plant Proteins, and Their Method of Separation. E. J. Candlin and S. B. Schryver: The Relationship of Pectin to Hemicellulose. E. C. Grey: Studies on the Nutrition of Pigeons. R. K. Christy and W. Robson: Estimation of Chlorides in Biological Fluids.

HUNTERIAN SOCIETY.

MONDAY, Dec. 5th.—7.30 P.M., Dinner at Simpsons Restaurant, Bird-in-Hand-court, Cheapside. 8.30 P.M., Discussion on Backache, to be opened by Dr. David Barcroft, Mr. C. Lambrinudi, and Mr. G. A. Macdonald.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Dec. 5th, to SATURDAY, Dec. 12th.—FELLOWSHIP OF MEDICINE. Lecture at Medical Society, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Dr. R. Travers Smith: Practical Hints in Medicine.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Special course, afternoons only.—INFANTS HOSPITAL, Vincent-square, S.W. Afternoon course.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Post-graduate course in Neurology. Every afternoon at 4 P.M. until Dec. 17th. Further information from the Secretary, Mayfair 2236.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, W.

MONDAY, Dec. 5th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Dr. Trevor Davies: Gynæcological Department.

TUESDAY.—11 A.M., Mr. Endean: Demonstration of Venereal Diseases. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients. 4.30 P.M., Dr. Pritchard: Diabetes Mellitus (lecture).

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 4.30 P.M., Mr. Donald Armour: Head Injuries (lecture).

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. MacDonald: Genito-urinary Department. 2 P.M., Mr. Bishop Harman: Eye Department.

FRIDAY.—10 A.M., Dr. Pritchard: Special Medical Treatment Clinic. 12 noon, Dr. Redvers Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Medical and Surgical Out-patients, Operations, Special Departments, daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 6th.—5 P.M., Dr. W. Griffith: Eczema (1).

THURSDAY.—5 P.M., Dr. W. Griffith: Eczema.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Dec. 6th.—3.15 P.M., Dr. C. M. Hinds Howell: Disorders of Sensation and their Clinical Significance.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

THURSDAY, Dec. 8th.—4 P.M., Mr. J. S. Joly: Clinical Demonstration of Urology Cases.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Dec. 8th.—4 P.M., Dr. Schlesinger: Complications of Pneumonia.

PEOPLE'S LEAGUE OF HEALTH.

THURSDAY, Dec. 8th.—6 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. T. Beaton: Brain and Nervous Symptoms.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, Dec. 9th.—3.30 P.M., Dr. Abercrombie: Brachial Neuritis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Dec. 6th.—4.15 P.M., Mr. J. P. Buckley: Femoral Hernia, its Ætiology and Treatment.

FRIDAY.—4.15 P.M., Dr. W. M. Roberts: Gastric Analysis in Clinical Medicine and Research.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

TUESDAY, Dec. 6th.—4 P.M., Sir George L. Cheatle: Some Recent Views upon Carcinoma as Applied to the Colon. Discussion to be opened by Prof. T. Price.

FRIDAY.—4 P.M. Case Reading and Discussion in which all medical practitioners are invited to take part.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Dec. 7th.—4 P.M., Dr. L. R. Lempriere: The Health of the Public School Boy.

CHADWICK PUBLIC LECTURES.

MONDAY, Dec. 5th.—5.15 P.M. (in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, W., Colonel P. S. Lelean: The Mind and Health.

Appointments.

BRAMWELL, J. CRIGHTON, M.D. Manch., has been appointed Honorary Consulting Physician to St. Mary's Hospitals, Manchester.

FISHER, S. W., M.D., B.Ch. Dub., Medical Inspector of Mines under the Coal Mines Act, 1911.

SMITH, S. A., M.D., Ch.B. Edin., Professor of Forensic Medicine in the University of Edinburgh.

SYMNS, J. L. M., M.D., B.Chir., Camb., District Medical Officer (Medical Referee) to the Scottish Board of Health.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Dis., Vauxhall Bridge-road, S.W.—Res. Sen. H.S. and Non-Res. Jun. H.S. At rate of £200 and £150 respectively.

Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.

Barnsley, Beckett Hospital and Dispensary.—H.P. At rate of £140.

Barnstaple, North Devon Infirmary.—H.S. At rate of £150.

Basingstoke, Park Prewett Mental Hospital, nr. Basingstoke, Hants.—Med. Supt. £950.
Birmingham, Queen's Hospital.—Surg. Reg. £100.
Birmingham and Midland Homœopathic Hospital and Dispensary. H.S. £150.
Brighton, Royal Sussex County Hospital.—Hon. Med. Clin. Asst.
Chichester, Graylingwell Mental Hospital.—Jun. M.O. £300.
Croydon County Borough.—Asst. M.O.H. for Tuberculosis. £750.
Derbyshire Royal Infirmary, Derby.—Ophth. H.S. £150.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.
Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.
Godalming, Surrey, King George V. Sanatorium.—Jun. Asst. M.O. £500.
Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Cas. Surg. O. and H.S. Each at rate of £100.
Leeds, Jewish Herzl-Moser Hospital.—Res. M.O. £50.
London Homœopathic Hospital, Great Ormond-street, W.C.—Three Res. M.O.'s. At rate of £100.
London Hospital, E.—Cardiographic Dept. Paterson Research Scholar. £400.
London Jewish Hospital, Stepney Green, E.—Hon. M.O. for Dept. for Dis. of Skin.
London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Manchester Babies Hospital, Burnage-lane, Levenshulme.—Jun. Res. M.O. At rate of £50.
Manchester Royal Children's Hospital.—Radiologist. £250.
Manchester Royal Infirmary.—Asst. M.O. £35.
Metropolitan Hospital, Kingsland-road, E.—Phys. to Dept. for Diseases of Skin.
Nigeria.—Four M.O.'s for Tsetse-fly Investigation. Each £660.
Perth Infirmary.—H.P. Also Jun. H.S. Each £75.
Plymouth County Borough.—Asst. M.O.H. £750.
Preston and County of Lancaster Queen Victoria Royal Infirmary. Two Hon. Asst. M.O.'s to X Ray and Light Depts.
Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O., H.P., H.S.'s, &c.
Reading, Royal Berkshire Hospital.—H.P. At rate of £150.
Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.
St. Bartholomew's Hospital, E.C.—Surg. Also Phys. to Skin Dept.
St. John's Hospital for Dis. of the Skin, 49, Leicester-square, W.C. Pathologist. £100.
St. Marylebone Hospital, Ladbroke-grove, W.—Third Asst. M.O. £300.
Salford Royal Hospital.—Res. Surg. O. £200. Also two H.S.'s., H.P., and Cas. H.S. Each at rate of £125.
Salford Union Infirmary, Hope, Pendleton, Salford.—Two Asst. Res. M.O.'s. Each £275.
Sheffield Royal Infirmary.—Two H.S.'s., Asst. Cas. O., and Jun. Aural and Ophth. H.S. Each at rate of £80.
Stamford, Rutland and General Infirmary, Stamford.—H.S. At rate of £200.
Stoke-on-Trent, City of.—Res. Asst. Tuberculosis O. £500.
Stockport Infirmary.—Asst. Surg. O. to Ophth. Out-patient Dept. Also Asst. Surg. O. to Aural Out-patient Dept.
Swansea Hospital.—H.S. to Ophth. and Aural Depts. £150–£200.
Todmorden Borough.—M.O.H. and S.M.O. £800.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non-Res. H.S.'s. At rate of £150 and £100 respectively.
Wigan Infirmary.—Third H.S. At rate of £150.
Willesden General Hospital, N.W.—Vacancy on Hon. Med. Staff.
The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Halifax (York, W.R.).

Births, Marriages, and Deaths.

BIRTHS.

CORNER.—On Nov. 22nd, at Welbeck-street, W., the wife of Dr. William Corner, O.B.E., Iraq Health Service, of a daughter.
PATEY.—On Nov. 23rd, the wife of David Howard Patey, M.S., F.R.C.S., of a son.

MARRIAGES.

LISTON—LESCHER.—On Nov. 23rd, at St. James', Spanish-place, W., Reginald Prosper Liston, M.B., Ch.B., of Milner-street, Cadogan-square, S.W., to Katharine Mary, eldest daughter of T. Edward Lescher, O.B.E., and Mrs. Lescher, of Birkdale, Lancs, and London.

DEATHS.

HALLIWELL.—On Nov. 26th, after a short illness, Thomas Halliwell, M.R.C.S., L.R.C.P., of The Rowans, Lowther-hill, Forest Hill.
MONRO.—On Nov. 21st, at Carlton-road, S.E., suddenly, the Rev. Charles G. Monro, B.A., M.B., B.C., Organising Sec. B.C.M.S., formerly of Ranaghat Medical Mission and Incumbent of St. Silas', Glasgow, Capt., late R.A.M.C.
MOORE.—On Nov. 23rd, in London, following an operation, Dr. G. E. Moore, of Redcroft, Maidenhead, aged 77.
ORAM.—Nov. 28th, after a short illness, in his fifty-third year, Walter Charles Oram, M.D., of 72, Rodney-street, Liverpool, son of the late John Earle Oram, of The Royal University, Dublin, and Professor of Experimental Science in King's College, Windsor, Nova Scotia, and beloved husband of Mabel W. Oram.
STEWART.—On Nov. 23rd, at Cleveland, Claremont-road, Surbiton, after a short illness, Cameron R. Stewart, L.D.S., D.D.S.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts

THE CALDECOTT COMMUNITY.

SINCE the speaker and chairman were held up by t fog, the general meeting of the Caldecott Community, fix for Saturday last, had to be postponed, but the children revue was ample reward to those who overcame the di culties of travel. Opened in 1911 as a nursery school St. Pancras, the Community became in 1917, at the su gestion of some of the parents, a country boarding-sch for slum children. The minimum fee of 10*s.* a week cov but a quarter of the cost of upkeep, and there is no assur income. Yet in spite of untold odds against it the Co munity flourishes, and those who have experienced t inspiring atmosphere of adventure and service that p meates it know that its break-up would be a real loss to t country. "The time has come," says the last annu report, rather pathetically, "when the Community c stand a little wealth; for no amount of wealth would al now the standard of simple life, at which it has arrived necessity and which by freewill it would maintain, believi it to be the happy mean between a life of deprivation a a life of opportunity and pleasant toil." No servants a kept, and the necessary work of daily life is shared children and teachers alike.

At present there are 44 boys and girls, of all ages fr 2 to 17. In addition to being a sociological experiment absorbing interest, the Community is also a research ins tute of the most severely practical psychology. The a is to give every child individual psychological considerati and close personal study, and most of the children of very complicated problems. The academic teaching almost entirely individual; the children work under system which allows them for the most part to plan th own lessons, and ample time is given to outdoor wo Dalcroze eurhythmics, scouting, and cubbing. The econo of the system is proved by the fact that, although only fo hours a day are given to study, no child has ever failed take his or her proper place in class when transferred to secondary school, and they are far ahead of their cla mates in physical fitness. Their crying need at the mom is for a playground, and it is typical of the Community th their chief appeal for financial aid is couched in the wo of a pupil's letter home: "And then, there's our play field: it's all mud in winter, and all we can do is to p tip-and-run in the backyard, with the buckets turn upside down for wickets—which Miss Hayward (she's c secretary) says is a scandal because they get so batte (but she doesn't play)—and when Harrod's van comes we have to break up the game till it goes, and Edgar always get in it, though he knows it means going to and upsetting the sides; and if you knock a ball over wall or through the kitchen window it counts out inste of a boundary."

An essential part of the scheme is the continuous c structive interest taken in all the old pupils. It is obvi that the experiment must stand or fall by the extent which it leads its children into suitable careers. Community is a training ground for the young worker well as for the young child, for girls fresh from school n put in a short time learning child and house manageme They could hardly find a happier place to learn in.

Last year a nativity play was produced, under the wat ful care of grown-ups; this year, in healthy reaction, children demanded to be allowed to produce a revue "by themselves." The result, consisting of a circus, tournament, a dialogue between Mrs. 'Arris and Mrs. 'Igg a Haydn ballet and the Joly, Joly Wat carol, followed a Christmas revel, will never be forgotten by anyone w sees it. Besides illustrating the amazing natural tal which all children possess but very few have the opp tunity of displaying, it has the haunting beauty of a creat masterpiece. It is to be played again on Friday, Dec. 9, and Saturday, Dec. 10th, at 4.45 P.M. On the latter d the adjourned general meeting will also take place a o'clock, and Dr. Crichton Miller will give an address. O the foolish or the unfortunate will fail to secure tickets fr Miss Potter (Caldecott House, Goff's Oak, near Cheshu Herts); the journey by road or rail is an easy one. Michael Sadler has described the work of the Commun as "one of the most interesting educational things England," and the keynote of it is sincerity and "deli in simple things," freedom from affectation and f standards. There can be few places where the real the ideal come so close together.

THE INDUSTRIAL ARTS.[1]

THIS is a short and clear history of the development the industrial arts, with special reference to their prac

[1] By Frederick J. Glass. University of London Press. 19 Pp. 511. 12*s.*

s educational factors. It is a useful and informative book, hich, while it is a guide to hand-training in education, akes an agreeable appeal to the general reader. We can nagine no better introduction to a knowledge of the umerous handicrafts, for the technical instruction is clear, hile at the same time a love of the beautiful nd a taste for work are encouraged. The range of he book is large, for it starts with a description of he habitation of the primitive cave, and proceeds to onsider in order the more advanced types of dwellings volved during the progress of civilisation. This guide to ie evolution of the structure of the house is followed by apters dealing with its furnishing, and thus there is introuced in a logical way information on the various employents of fabrics—metals, leather, clay, glass, and so rth. As an example of the simplicity of the teaching the tes on furnishings show how the doll's house may be holstered, and on this the use of tools, the mechanism joints, and the history of furniture are made to depend. the section which deals with transport, Mr. Glass shows keen appreciation of the curves exhibited by marine ssels, and he stresses the educational value of the observaon of boats and the attempt by children to fashion them en on seaside holidays. The final section on trees should velop a love of nature and encourage any latent artistic ulty in the pupil. The book is well and copiously strated, and its author, who is headmaster of the School Arts and Crafts at Doncaster, writes evidently from ll knowledge of the fine results that may be obtained from ch instruction as he offers.

A READING DESK FOR THE INVALID.

WE have received from Mr. H. H. Arnold, of 81, St. orge's-road, London, S.W. 1, an appliance which he has med the "Readeasy" and which is intended primarily enable invalids to read a book without in any way tting a strain upon the arms or hands. To the sides and ver border of a light tubular U-shaped metal frame, ulded to the contour of the body, is attached an adjustable ap to be suspended from the neck. Projecting from the me, and adjustable as to inclination, is a narrow shelf holding a book. There are conditions where this reading sk should prove of use in illness or convalescence, while traveller on board ship would also on occasion find a for the invention. And for all of us the apparatus might d to the comforts of the armchair.

MEDICAL WOMEN AND THE STUDY OF MENTAL DISEASE.

MEDICAL women who are interested in the problems of ntal disease have formed an association for friendly ationship and discussion of their common problems. e second meeting was held at the Lyceum Club on v. 18th, by invitation of Dr. Bertha Mules and under chairmanship of Dr. E. Casson. After lunch the subt of occupational therapy was discussed. Dr. Jane lker described the varieties of work and handicraft d for tuberculous patients at Nayland. Dr. Casson phasised the danger of providing employment irrespecve of the patient's therapeutic needs, and referred to the tus of the occupational therapy officer, who should have ct relationship with the doctor, she thought, and should be under the direction of the matron. Miss Phillips cribed the initiation of occupational therapy at Virginia ter, and urged the medical profession to get this work er proper control from the start, lest it fall into the ds of quacks. Another question discussed was whether occupational therapy should be carried on in the wards, re apathetic patients might be attracted and drawn in, n a special department to which the patients would be en for so many hours each day. The general opinion ned to be that the two methods dealt with two different ses of patient, and both should play their part. Dr. M. Gamble pointed out that occupational therapy could ssfully begin while patients were still confined to bed. eral speakers emphasised the importance of providing loor work for women patients. Miss F. Gribble described work of the Association of Occupational Therapists in ng to organise the work and the workers, and to provide ntral bureau and a standard of training. After tea C. Shearer opened a discussion on the treatment of the rtified patient. All were agreed that there was a king lack of adequate treatment for these people, and establishment of clinics in every town was urged. The ing of these clinics was a matter of some difference of ion, but most speakers thought that the senior medical er should be a member of the staff of a mental hospital, e assistants might be recruited from among local practiers and part-time junior officers in mental hospitals. er urgent needs were for more hospitals like the Lady hester Hospital at Hove and St. Andrew's Hospital at thampton, and for trained social workers.

edical women who wish further particulars can obtain a from Dr. I. G. Wilson, 154, Clarence Gate-gardens, N.W.1.

THE PRESENT STATE OF THE MEDICAL PROFESSION IN JAPAN.

THE *Internacia Medicina Revuo*, the official organ of the Association of Esperanto Doctors, for November, contains several articles of professional interest and a further small instalment of a new Esperanto Medical Dictionary. In addition, there is an account of the present state of the medical profession and medical organisations in Japan by Koh-Itabashi, which states that while the majority of medical men in Japan have private practices, the difficulty of making a living becomes more and more hazardous, although the number of doctors in relation to the total inhabitants remains stationary. It would appear that the poorer classes are increasing in number, the writer including in these classes small tradesmen and manufacturers, the cause of the increase being attributed to the accumulation of capital in the hands of the few. Another factor in the depreciation of medical practice is the unequal distribution of doctors among the population. Official figures are given which show that there are too many doctors in the urban areas, particularly Tokio and Kioto, and too few in rural parts. With regard to organisations for medical treatment of the poor in Japan, the following particulars are given: (1) medical school clinics, where a definite number of sick are treated free in order that instruction may be provided for medical students; (2) medical organisations supported by private philanthropy and philanthropic bodies—(*a*) "Saiseikuai," founded in 1911 by imperial donations, where the sick poor are treated free on the recommendation of the administrative body of a town or village; (*b*) the Red Cross Society, which does not function in peaceful times; (3) medical organisations supported by public corporations—these comprise a number of hospitals for indigent consumptives, lepers, and insane people; (4) medical organisations in industrial districts—(*a*) in factories (not all factories, however, have such organisations and only 43·4 per cent. of workers and their families are treated at actual cost); (*b*) mining localities, where workers and their families are treated at actual cost; (*c*) industries supported by the Government, in which workers are treated free and receive during the period of treatment eight-tenths of their daily pay, their families being treated at actual cost. The *Internacia Medicina Revuo*, which is published in France, can be consulted at the offices of the British Esperanto Association, 142, High Holborn, W.C.

HEALTH CONDITIONS IN TANGANYIKA.

FROM a report to the League of Nations on the administration of Tanganyika territory for the year 1926, it appears that the population, according to the census of 1921, was as follows: Europeans, 2447, of whom 1598 were British subjects; British Indians, 9411; Goans and Portuguese Indians, 798; Arabs, 4041; Baluchis, 352; unclassified non-natives, 389; natives, 4,107,000. Since 1921 there has been a considerable increase in the European population, which is now about 4200; similarly, trade development has brought into the country a number of Asiatics as storekeepers, clerks, and artizans. The total native population is now estimated as 4,319,000, as against the 4,107,000 recorded at the census of 1921, but it must not be assumed that there has been a general increase of population, but rather that the enumeration is now more accurate In a few districts the registration of native births and deaths has been made compulsory, but it is not possible to guarantee the accuracy of the statistics which have so far been obtained. There is no doubt that a large number of births are not registered owing to the traditional native reluctance to announce such events.

For the financial year 1926–27 the approved estimate of expenditure on medical and sanitary services amounted to £190,616, as compared with £147,701 for the previous year, and the position as regards staff improved materially. The number of European medical officers employed increased from 39 in 1925 to 46 at the end of 1926, the number of Asiatic assistant, senior sub-assistant, and sub-assistant surgeons from 39 to 50, and the number of private doctors registered as medical practitioners in the territory from 8 to 14. These figures do not include the headquarter staff, laboratory staff, entomologist, and dental surgeons. A new hospital at Dodoma was opened, and certain sections of the Central Lunatic Asylum were completed. Several new medical stations were placed under the care of sub-assistant surgeons or compounders.

In regard to attendance of natives at Government hospitals, whilst the in-patients figures show a diminution of the numbers admitted, the numbers of out-patients have increased by a considerable amount. This increase is due to the beneficial results obtained in the treatment of yaws and syphilis with bismuth, which attract large numbers of the sufferers to apply for relief. The reduction in the number of in-patients is believed to be due to the increased facilities afforded for early treatment, the improved

conditions generally under which labour is employed, the expansion of sanitation, urban and rural, and the gradual awakening of health conscience in the African population at large. The total of in-patients in 1926 was 26,640, and of out-patients 342,653. There was a total of 946 deaths recorded during the year, a number of which were due to hookworm and pneumonia. Distinct progress has been made in the direction of maternity and child welfare, and there were 18,969 attendances at the clinics during the year.

While better feeding is provided at many plantations, and the expansion of the medical department has made treatment more accessible than in the past, the local situation at several locations still requires improvement. It is hoped that the organisation for the training of African district sanitary inspectors which is being established will prove of value in this direction. A small school for the training of dispensers in charge of a European instructor has been inaugurated. The movement for providing tribal dressers is an entirely new departure, and is exciting considerable interest among the chiefs. Standard sets of equipment and drugs have been drawn up, and are obtained from London by the provincial commissioners. A pamphlet of instructions, outlining simple methods of treatment and the usage of the drugs, dressing, and equipment, both in English and Kiswahili, was printed and issued. The training includes a short course of elementary practical sanitation such as might be applied to improve the unhygienic conditions of rural villages. Drugs for the treatment of worm infestations, such as hookworm, roundworm, and tapeworm, are provided. Much alleviation of illness amongst the outlying district populations, at present beyond the range of our medical units, should result. Over 30 tribal dressers have already been trained, and a similar number is in training.

A special medical officer was detailed for duty in the Moshi district towards the end of the year, for the purpose of conducting a full investigation into the incidence of tuberculosis amongst the tribes inhabiting the Kilimanjaro and Pare mountains. The interim reports received indicate the necessity of employing one or more medical officers on this work for several years, if not permanently. Progress continues in the campaign against yaws and syphilis. Several medical missions have undertaken treatment with drugs and equipment supplied by the medical department, and 11,599 cases of yaws and 1825 cases of syphilis have thus been treated. The total cases dealt with in the last three years are as follows —

	Syphilis.	Yaws.
1924	4,377	20,741
1925	11,288	74,638
1926	17,751	96,624

The incidence of dangerous infectious diseases throughout the territory during 1926 was very low. A total of 20 cases of small-pox was reported from five districts; no deaths occurred. Cerebro-spinal fever showed no signs of becoming epidemic; only light cases, with four deaths, occurred. With the exception of six fatal cases reported from the remote district of Shirati, an endemic area situated on the Tanganyika-Kenya border, no cases of plague were reported in the whole of the territory. Influenza, as in previous years, has been responsible for the largest number of deaths—viz., 209—the number of cases is not known. All but four of the deaths occurred in the districts of Usambara, Rungwe, and Tabora; the two former are mountainous, cold districts, while in Tabora, although the altitude is not so high, bitterly cold nights occur at certain seasons. In all three districts the climatic conditions are exceedingly favourable for the production of complications, such as pneumonia, amongst an ill-clad population suffering from even a mild epidemic of influenza.

During the year six medical officers have been seconded exclusively for sleeping sickness work. No new foci of infection have been discovered, and the activities of the sleeping sickness staff have been mainly concentrated on the infected areas in the Tabora and Ufipa districts. The policy adopted in this enormous area, approximately 10,000 square miles in extent, has been to concentrate the population in fly-free clearings. Tribal organisations have been maintained, and the people still live under the control of their own chiefs. Up to the end of 1926 seven clearings had been completed, extending over a total area of more than 60 square miles, while two more clearings are still being made. 7500 square miles of fly-infested forest have now been evacuated, and the inhabitants, numbering approximately 14,500, have been accommodated in the clearings. The Masoma-Ikoma infected area is still under investigation. From observations made by the assistant-bacteriologist, who himself became infected with Rhodesian sleeping sickness in this district, it appears probable that the disease is endemic throughout the whole of the fly-infested area round Ikoma, and in a north-easterly direction towards the Kenya border. The population in this area d not as a general rule live in intimate contact with the fly, but acquire infection while travelling through fly belt and when engaged in hunting and fishing expeditions. The disease shows no sign of becoming endemic, and unt the fly can be eliminated, or the inhabitants removed t fly-free areas, sporadic cases will continue to occur. Treat ment, as in previous years, has been almost exclusively b Bayer 205, Fourneau 309, and tryparsamide.

The Tanganyika territory, it is explained in a geographica and historical note, consists of that portion of the forme colony of German East Africa which, under the Treaty c Peace with Germany, the Principal Allied and Associate Powers agreed should be administered under a mandat by His Britannic Majesty. The coast line extends for distance of approximately 500 miles from the Umba Rive on the north to the Koruma River on the south. Along th coast lies a plain, varying in width from 10 to 40 mile behind which the country rises gradually to a platea constituting the greater part of the hinterland. This platea falls sharply from a general level of 4000 feet to the lev of the lakes (Tanganyika, 2590 feet; Nyasa, 1607 fee which mark the great Rift Valley extending northwards t Lake Naivasha. The seat of government is Dar-es-Salaa (population approximately 25,000), a modern town founde in 1862 by the then reigning Sultan of Zanzibar, and sul sequently occupied by the Germans in 1887.

SMITH'S PHYSICIANS' AND SURGEONS' VISITIN LIST, 1928.

THIS well-known diary, almanack, and book of engag ments is now in its eighty-second year of publication. Th pages are ruled for the convenient recording of visits and f entering engagements, while space is provided for addresse cash, memoranda, and so forth. The size of the book slightly in excess of 6 in. by 3 in., and it can be obtained wit spaces for 75 or 100 patients and with or without journ rulings. Bound in cloth boards or in morocco with tuc pocket, and pencil, the price varies from 7*s.* 6*d.* to 12*s.* Th publishers are Messrs. Hazell, Watson and Viney Ld., 16 Shaftesbury Avenue, London, W.C. 2.

TREMATODES IN MAN.

IN bringing out a Reference List of the Tremato Parasites of Man and the Primates (*Parasitology*, Sept. 30t 1927, p. 338), Dr. William Nicoll has rendered a distin service to helminthology, as well as to the practical clinicia The parasites which infest man may usually be found other mammals, more especially domestic animals, but spite of numerous investigations, it must be admitted th our knowledge of several of them remains incomplet Dr. Nicoll gives tabular lists of the parasites and the mammalian hosts arranged in a systematic manner, togeth with an extensive synonymy, and notes their situation the body. The paper terminates with a particularly comple bibliography.

CHOCOLATE AND COCOA.

WE have received from Messrs. Cadbury Brothers, Lt of Bournville, Birmingham, specimens of their well-know chocolates, the samples sent being known as King Georg Mayfair, and Carnival chocolates. Specimens have al been sent of plain eating chocolate, of chocolate with bitt or orange flavouring, and of chocolate in which assort fruits or nuts are embedded. In addition we have receiv a specimen of Bournville cocoa. The hygienic conditio under which the wares of the Cadbury Bros. are produc are known to be of the best; all these things are not on of nutritional value, but are also pure and appetising.

MEDICAL CALENDAR.

WE have received a copy of the Medical Art Calendar f the year 1928 published by J. Philip Kruseman, Noordeinde 9 The Hague, Holland. The calendar, which has n reached its tenth year of issue, contains some 27 photograph reproductions of medical interest, all well reproduced. might be expected, the pictures selected are mostly of Dut origin, many will be familiar to our readers, while t originals of others are to be found in much-frequent galleries. A feature of the collection is the extraordina popularity among the Dutch of dentistry as a pictor subject. The price of the calendar is 6*s.* post paid.

The *London College of Pharmacy for Ladies*, 7, Westbour Park-road, W. 2, which is under direct medical supervisio offers a nine months' course of instruction to women preparation for the Apothecaries' Hall Diploma in dispensi The training facilities at the College are good and the cou may be recommended to women whose abilities are suit to this kind of work.

An Address
ON THE
UBCONSCIOUS FACTOR IN MEDICINE.

Delivered before the Devon and Exeter Medico-Chirurgical Society on Oct. 19th, 1927,

Y BEDFORD PIERCE, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE RETREAT, YORK, AND EX-PRESIDENT, ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

FROM time immemorial man has realised that mind not limited by consciousness. Plato says: "In all us, even in good men, there is a lawless wild-beast ure, which peers out in sleep." I believe we owe Savage the simile of the iceberg; the conscious nd is that part of the iceberg seen above water, the greater part, at least five-sixths of the whole, nseen below the surface, and it is this which is most ngerous to mariners. Coleridge, whose poem Kubla an was composed during sleep, considered that the ater part of mind was outside consciousness. hese views implied some degree of mental activity he mind apart from consciousness, but only in our n time has a theory of this activity been developed its application to medicine recognised. The innings of this advance were in 1880, when Dr. ef Breuer, a Viennese physician, conceived the a that hysterical symptoms might be dependent on t experience, and discovered a new method of utment. A girl suffering from severe hysteria was notised, and whilst in the hypnotic state she was ed to search her memory for incidents that arose n she had nursed her sick father. She was induced ive these scenes over again and the hysterical ptoms disappeared for good. This preceded the stigations of Charcot and Janet into the same ject. In 1895 Breuer, in conjunction with Dr. nund Freud, published the "Studien über teria" and later Freud, following his own line, eloped his theory of the unconscious and devised process of psycho-analysis. Such was the nning of the modern psychology, which has red our outlook on human life in so many directions. the title of this paper I have used the word bconscious" in a general comprehensive sense, wishing to be bound to any psychological theory. quite unnecessary to give any account of modern s; the teachings and the language of Freud are very text-book, they permeate our novels and azines, and are even shown in the moving pictures. ay be excused, however, if I mention one or two mptions of modern psychology.

he first is that desires and experiences unacceptable he personality can be repressed and entirely otten. This repression is stated to be an active ess and not merely a passive forgetfulness. It is due to conscious voluntary effort. The second mption is that the repressed material is not ant or quiescent within the unconscious mind, rather active and disturbing; it finds expression number of morbid symptoms or peculiarities, and e source of anxiety, phobias, and hysteria.

is extremely difficult to describe a case properly. details are so voluminous that some kind of act is inevitable. Yet it is easy to give a distorted by the mere omission of particulars that seem portant. An account, moreover, can give little of the quantity of work involved. It is often ssible to relate a case without a breach of dence, whilst to disguise a story is very unsatis-ory. Further, in this department of medicine rts are apt to be coloured by the personality of the er. Lastly, it is often impossible to follow up sufficiently to estimate fairly the results of ment.

SOME ILLUSTRATIVE CASES.

I am indebted to Dr. Hugh E. Wingfield for permission to publish the following case, concerning which I have also some personal knowledge.

A girl of 14 complained of nervous fears of full ten years' duration. In company and at boarding school there was little amiss; but at home, where she had her own bedroom, she slept badly and had night terrors. She would not go into certain rooms alone and she was seen to look furtively behind her, apparently to see whether anyone was following her. She would bang doors hard as if she were shutting someone out. She was intelligent and could not say why she did these things.

Under treatment by Dr. Wingfield she was able to recollect childish incidents which had been utterly forgotten. They were, briefly, as follows. When 4 years of age she had a French nurse who was fanatically religious and who told her that unless she kept a crucifix under her pillow the devil would certainly get her! By degrees every detail was recalled—the nurse's staring eyes and her strange conduct. It so happened that soon after this the nurse had become insane. The child had personified the devil as a giant negro with a big stick—a terrible being to meet, especially in the dark. The clearing up of the cause for these fears resulted in a rapid and complete recovery. Ten years have elapsed and there has been no return.

There can be little doubt that if these forgotten incidents of early childhood had not been elicited the phobias would have continued and made life miserable. The parents were altogether unaware of the conduct of the nurse, and the child herself was too young to be able to complain.

Dr. Rivers's classical case of claustrophobia is another good example.

A case of hysterical vomiting may also be mentioned:—

A clever and apparently healthy school-girl was troubled with persistent vomiting. This continued until a forgotten early incident was called to mind. When a very small child an elder sister had compelled her to look at a mummy which her father had brought back from Egypt and thereupon she vomited. Though the episode was forgotten the habit of vomiting continued until the conscious revival of the experience produced a cure.

These cases sufficiently illustrate the important conclusion that long past experiences quite beyond unaided recall are a cause of morbid symptoms. They also show, contrary to the teachings of the pure Freudians, that such experiences are not necessarily sexual in nature. They may be the result of conflict between other instincts, as was abundantly shown during the war when psychoneuroses of many kinds arose from the conflict between duty and self-preservation, or, in other words, between the herd- and the ego-instincts.

The Sexual Factor.

We must not, however, underestimate the great importance of the sexual instinct in psychopathology, especially if the term sex is extended to include maternal instinct. Though most authorities dissent from Freud's theories of infantile sexual experience, it cannot be denied that we find many of the symptoms he describes during the investigation of our patients. That these symptoms are explained by an œdipus-complex or by narcissism is, however, doubtful.

A married woman, aged 42, with no children, consulted me on account of insomnia, intolerance of loud sounds, noises in the head with ringing of bells, fits of weeping, inability to attend to duties, and loss of interest in life. She feared she was going mad, and would become suicidal. The duration of her illness was two years. The uterus had been stitched up to prevent retroversion. Had had many changes of scene. Had tried Christian Science. Had recently had six weeks Weir Mitchell treatment.

Previous History.—Unhappy childhood. Mother and step-mother both alcoholic. At 35 had begun morbid blushing. Naturally artistic, musical, and much in demand socially. Husband 13 years older. He did not care for gaiety but was not jealous. Patient was never pregnant. General health good.

So far the case seemed an ordinary depression, possibly connected with the operation and approaching menopause. One fact suggested a repressed complex. Since her illness she had slept apart from her husband, and she mentioned incidentally that when she said good night she broke into a fit of weeping.

Elicited.—Want of harmony with husband. She had long cherished a secret affection for another man and dwelt on it in day-dreams; there had been no impropriety, but she persuaded herself it was a beautiful experience. Jung's word analysis gave a long reaction to the word "sympathy." There were also long reactions to the words "despise," "low," "big," "long"—which referred to repressed facts of personal history. After about five weeks analytical treatment there was an emotional outburst when a strange and isolated incident was recollected. This brought to light the internal conflict between her duty to her husband and her ideals (for she was a woman of high principle), and her lower desires and unfulfilled wishes.

The genesis of the greater part of her symptoms was now cleared up. The neurosis in a sense gave relief, it entailed long absences from home, it gave ample opportunity for self-pity, and the indulgence in pleasurable day-dreams. The patient herself was quite unaware that these facts had any relation to her illness; indeed, the possibility had not entered her mind. Fortunately, she was a woman of character and determination, and when the position was made clear she faced it courageously. The sleeplessness disappeared, she became cheerful, and was soon anxious to return to her husband.

This happened 20 years ago and there has been no relapse; and she is leading an active and useful life.

Here is a case of automatic wandering:—

A lecturer at a technical college, after a bad night, disappeared from home at 11 A.M. leaving a note saying he had lost all hope. He also left an obscure message in German referring to departure for ever and ever. He returned on his own accord at 7.30 P.M. and could not say where he had been until he had found himself on a seat over 300 yards away. He was cold, footsore, and had worn out the backs of his trouser legs with walking.

There had been two previous attacks, the first when, after a difference with his father as a boy, he had been lost some hours and could not remember what he had done. The second attack occurred six weeks after marriage, when he was depressed and confused and said something to the effect that it would be easy to strangle his wife. This he could not afterwards recollect. His brother-in-law thought him hysterical. He rapidly recovered and gave a lecture as usual the same evening.

There was no history of fits or of petit mal. He was popular and very hard working.

His medical man had discovered the immediate cause before I was consulted. Although married, he had abstained from sexual intercourse apparently for financial reasons. When normal marital relations were established there was complete relief and the depression and irritability passed off.

Why under such circumstances mental dissociation should occur I do not know. It is evident that in this individual any strain tended to be expressed in this way.

Sometimes investigation discloses internal strains for which no direct relief is possible. One of the most unsatisfactory is the homo-sexual tendency, where the company of the same sex alone gives gratification. Some have attempted to explain the tendency by assuming a diversion of natural instinct through a "mother-fixation" in early infancy. I am inclined to think it is really due to a congenital disposition of sex elements. However it arises, many of these persons are condemned to perpetual repression, and unless they understand their own peculiar nature, life is hard and hopeless. When, however, the position is grasped they can devote themselves to hard and useful work and find consolation in altruistic effort. Similar difficulty arises in marital incompatibility, which, but for careful investigation by the physician, might not have been recognised as the cause of a neurosis.

CONTENT OF THE SUBCONSCIOUS MIND.

When we attempt to consider the nature of the subconscious mind we are at once in very deep water, and may easily be carried away by metaphysical speculation. The Freudian school habitually use the term "the unconscious," thereby suggesting an entity with special functions. Freud is a determinist, and for him every symptom has a cause in the experience of the individual, and he concludes that there is some physical basis in the nervous system for every mental process. The unconscious therefore contains primitive ideas and instinctive desires as well as repressed material. The deeper the analysis goes the more the native instincts are laid bare. Thus successive layers as it were of character-formation are peeled off unt the natural elementary mind is reached. This devoid of morals and is only influenced by the pleasu pain principle. It seeks the gratification of its o desires regardless of anything outside. Freud furth teaches that if the investigation be carried far enou the instinct concerned is found to be sexual in eve case.

The Zürich school, founded by Jung, finds in t unconscious elements that are not individual a personal. Jung states that if the analysis be continu after all the individual experiences are elicited, n elements appear which may be dangerous. He assun the existence of a "collective unconscious," and s "We are now obliged to differentiate a perso unconscious and an impersonal one, the absolute collective unconscious, which is detached from wl is personal and is absolute and universal." Speak of the content of this he says: "The primord images are the most ancient and deep thoughts mankind. They are feeling just as much as thoug and might be termed thought-feelings." Here Ju finds the common source of myths, primitive religio and the idea of soul, spirit, god, fertility, migt prestige, and, strange to say, curative remed Hence it would seem that the widespread notion t every disease must have a specific remedy, and ev poison an antidote, comes from the collective unc scious common to all men.

There is no doubt that our unconscious mind h us in our thinking. I suppose all of us have fou that after a good night's rest difficulties are of solved that formerly had baffled us. Readers "Across the Plains" will remember that Steven tells us the dramatic window scene in "Dr. Jekyll Mr. Hyde" came to him in its entirety whilst he asleep and dreaming.

Some years ago, when on holiday, I met a Scot manufacturer who told me that one night he aw finding himself declaiming a long poem. His urged him to write it down at once, but he could recollect one stanza—

> And what are thoughts,
> But birds which light and fly?
> And what are words
> But traps to catch them by?
> Many are dead and cast to Lethe River
> But some survive as joys encaged for ever.

My friend had never written a line of poetry in life; he could recollect no source. I made inq through a literary paper and could trace nothing it. It is, of course, possible that a memory store his mind had reappeared in these striking lines, it is said there is nothing new under the sun. explanation, however, seem insufficient.

Rivers says:—

"Many lines of evidence are converging to show tha great accomplishments in human endeavour depen processes which go on outside those regions of the mi which we are clearly conscious. There is reason to be that the processes which underly all creative art, litera or science take place unconsciously or at least unwitti It is an interesting point whence comes the energy of w this work is the expression."

All will probably agree that some kind of thin takes place in the subconscious mind. The awk phrase "unconscious cerebration" represents actual process. In a recent number of the *Journ Mental Science* (July, 1927) Dr. Winslow Hall r to the subconscious measurement of time, and he conducted a series of experiments which show clusively that a time-sense exists and that it w best below the threshold of consciousness. He refers to the extraordinary accuracy of time-meas ment shown in post-hypnotic suggestion.

This strange unexplored region of our minds con stored memories of countless unremembered ex ences, and in some way these are integrated to our characters. When we are confronted wit emergency our response is rarely thought out, b usually spontaneous; its general nature is determined by decisions and opinions taken long and apparently forgotten. But this conception

help in understanding what goes on below the reshold. Whence come inspiration and originality? hat directs the subconscious flow of thought? hat launches our dreams? We may also ask whence mes the power to appreciate the three great concepts truth, beauty, and goodness?

In attempting to look into these inner mysteries can hardly see farther than Matthew Arnold in The Buried Life"—

> "But often, in the world's most crowded streets,
> But often, in the din of strife,
> There rises an unspeakable desire
> After the knowledge of our buried life,
> A thirst to spend our fire and restless force
> In tracking out our true, original course;
> A longing to inquire
> Into the mystery of this heart which beats
> So wild, so deep in us, to know
> Whence our thoughts come and where they go.
> And many a man in his own breast then delves,
> But deep enough, alas, none ever mines:
> And we have been on many thousand lines,
> And we have shown on each talent and power,
> But hardly have we, for one little hour,
> Been on our own line, have we been ourselves."
>
> * * *
>
> "Yet still, from time to time, vague and forlorn,
> From the soul's subterranean depth upborne
> As from an infinitely distant land,
> Come airs, and floating echoes, and convey
> A melancholy into all our day."

Must we always assume that the mental processes ch go on without our knowledge are regressive in ure and represent the "wild beast" within us all? en dealing with subject matter outside our ken we not be sure of anything. Yet there is evidence that unconscious mind can be trained. Stevenson tells he trained his mind so that dreams, which at one e were distressing in the extreme, became useful, he speaks of the help he received in his work from e little people of his dreams." So far as dreaming oncerned, I feel sure that dream incidents are not ely the wish-fulfilments of instinctive desires. ients have often told me they never dream, and when asked to write down their dreams for the pose of analysis, almost invariably they bring ity of dream material. Moreover, I am not sure this is solely the expression of the unconscious d, and I fancy that patients will sometimes in d faith dream in accordance with expectation.

single woman consulted me on account of obsession of y unpleasant nature which caused her constant distress. had been a cheerful, active church worker and had ed her parents through long illnesses in the most lfish way. Many years before she had been engaged to arried, but the engagement was broken off by mutual ent. This she had never regretted; the man was now ied happily and had children. In the course of an sis these facts and many other details of her personal ry were elicited and, as so often happens, it transpired all questions of sex had been taboo during her childhood adolescence. These were frankly ventilated, and e long she began to dream repeatedly of her former é, Mr. S. Finally, she came to me with a dream to the that she had met Mr. S. in a large store and he was attentive, but she did not respond to any advances ade; and then he went to another department and ht her a doll.

is rare for the symbolism of a dream to be so trans- t as this, yet the patient did not at first grasp its icance. I had an uncomfortable feeling that the peutical conversations had, shall I say, prepared the nscious mind so that the dream appeared.

ortly after this the patient improved and remained better, but was not really well for many years.

MENTAL "MECHANISMS."

eud, in elaborating his psycho-analytical theory, ntroduced a number of technical terms to describe al processes which take place unconsciously. e are now so familiar that they require no nation. By repression painful conflicts become nscious, and the repressed material causes onversion, hysterical symptoms; by dissociation, es; by projection, phantasies and delusions; by ssion, a return to infantilism, and so forth. On other hand, by sublimation, the repressed energy an outlet in more healthy ways, as hard work or altruistic effort. These terms are part of a large vocabulary of words in everyday use in Freudian psychology. I have always felt an objection to the use of words having a spatial meaning in reference to mental processes, though they may be unavoidable. Breuer says: "All too easily one gets into the habit of assuming that behind a substantive there is a substance." That we are using metaphors in speaking of mental processes is forgotten and the metaphor itself is manipulated as a material thing. This has happened to the terms conversion, projection, substitution, &c. The widely used term "mental mechanism" is objectionable in describing the activities of the mind. Moreover the Freudian theory seems to imply there is a conservation of mental energy. Thus Freud says: "In both cases the libido behaves like a stream, the principal bed of which is dammed; it fills the collateral channels which until now have been empty." I find such terms misleading. Can there be any mechanism in mind, or is it proper to assume that repressed ideas must find an outlet, and that if diverted or held back, they are governed by the laws of hydrostatics?

Mental energy is something living, and we must not assume that it is fixed or limited in quantity until some means of measuring it has been discovered.

The late Dr. Maudsley says in one of his lectures:—

> "An impassable gulf lies between the measurement of the perceived energy—that is the objective energy which can be handled and for which all the world can agree on a common unit of measurement—and the subjective state, which is intangible and for which no common unit of measurement is possible. How measure the thrill of a pang of grief? The heat of a flash of rage? The corrosion of an envy? The vibrations of a ray of hope? The leap of an inspiration? How sound the depths of sympathy? or estimate in millimetres the height of a vaulting ambition?"

ANALYSIS AS A THERAPEUTIC AGENT.

The term psycho-analysis should be restricted to the technique introduced by Freud, for it presumes the validity of his theory of the unconscious. The process consists of "free association," in which the patient frankly and unreservedly gives expression to any ideas that enter his mind. This is supplemented by dream analysis, in which free association is applied to the material elicited from dreams. Any kind of suggestion is disclaimed. Thus Stoddart writes:—

> "The doctor says as little as possible, but merely keeps the patient to any line of association initiated by him (the patient). He tells the patient absolutely nothing and scrupulously avoids suggestion of any kind."

Stoddart adds, however, that it is permissible "to comply with his request to give an explanation of a psychical mechanism which has become obvious to him but incomprehensible." On the other hand, Freud himself speaks of the great psychical effort required by the physician to overcome the barrier created by repression. He also says:—

> "A psycho-analysis is not an unbiassed scientific research, but just a therapeutic invention. The physicians give in psycho-analysis every time to the patient the respective expectation-ideas by means of which he shall be able to recognise that which is unconscious and seize it . . . without such help no one can get on."

Evidently the master is sounder than his pupils. Surely it is obvious that during intimate conversations of an hour's duration five or six times weekly for months together, the physician continually employs suggestion, whether he wishes to do so or not. Moreover, the explanations he gives inevitably create a bias, and his own opinions must be slowly conveyed to his patient.

Although more than 20 years have elapsed since psycho-analysis was introduced its place in medicine is uncertain. It has achieved striking success in the treatment of intractable cases of hysteria and other psychoneuroses; but its use is limited, for it makes a great demand on both physician and patient. It involves such an extraordinary expenditure of time and trouble that only in very exceptional cases does it appear practicable.

Modifications of Freud's methods have been widely adopted, and, I have little doubt, will displace the original psycho-analysis. They may be called psychological or mental analysis, which is not limited in practice by any preconceived theory; moreover, suggestion is openly used. Some practitioners advocate hypnotism, as Freud did originally, and others aim at creating a quiescent half-conscious condition—the hypnoidal state—to facilitate analysis. In this state suggestion is not used directly to promote recovery, but indirectly in order to uncover the repressed ideas and conflicts. Often quite a few conversations suffice to elucidate these factors and render possible a new adaptation for life's demands.

Some mention must be made of "transference," a term introduced by Freud to denote the altered emotional attitude of the patient towards the physician. This may be either one of affection or of hatred. Freud and his school say that infantile sexual love is liberated, and is no longer fixed on the father or the mother, but is transferred to the physician. However this may be, there is no doubt that the physician frequently obtains an extraordinary ascendancy due to the patient's passionate regard for him. Analysts are apt to make light of this, considering it a mere episode in the course of treatment, which will pass away as the analysis progresses, but it is easy to see that delicate situations may arise, and the integrity of the physician may be challenged.

In the endeavour to understand a patient's conflicts we are frequently confronted with ethical problems. The physician cannot escape by saying that these are no concern of his, for the patient needs a new modus vivendi, and the situation has to be faced. Even though the physician offers no opinion and gives no advice, his own attitude to the ethical problems of life can hardly fail to produce an effect. Here is one of the greatest difficulties of analysis. Before we can recommend a patient to undergo this searching investigation we must know something of the analyst. The question is a delicate one. Judging from the published writings of certain psycho-analysts, their fitness for conducting the education of a young person is questionable. Which of us is really fitted to give an opinion on moral issues? Our medical education avails us little in these matters.

Another tendency that seems hurtful is the divorce of psycho-analysis from general medicine. I have heard of analysts who refused to make a physical examination and said that this must be done by some other physician. I have also heard of the prolonged analysis of patients with organic nervous disorder such as disseminated sclerosis. We must be physician to the whole patient—body and mind alike.

Though I have criticised the psycho-analytic theory, I do not wish to undervalue its contribution to medicine. It is true that some of the developments of the theory are so repugnant to common sense that the whole position is jeopardised. Sometimes, when we read psycho-analytical literature, we are amazed that medical men can give serious attention to such questionable material. It is not that I object to the frank discussion of the many indecencies that disturb the minds of our patients. The suffering caused by obsessions of this nature is often intolerable, and I have known a patient driven to suicide by them. It is rather the conclusions of the analysts themselves which seem to offend. Thus a patient dreamt he passed through a long tunnel and eventually came out into open and beautiful country. This was confidently interpreted by the analyst to be a symbolic expression of the personal experience of the patient whilst being born!

This is very unfortunate, for Freud has given to medicine a new orientation. The conception of an unconscious "flight from reality," by which persons faced with an intolerable situation escape by a psychoneurosis, is of real value. The process of re-education which leads a patient to recognise this, and consequently to face his underlying conflicts, is an important therapeutic procedure.

The problem, however, is not solved. At present it seems impossible to say why persons react in su diverse ways to these internal conflicts. One becon hysterical, another has an obsession, a third a pseu epileptic fit, whilst a fourth may drink or take to dru or a fifth retreat from the world and live in a state phantasy. Though the mental source of a sympt may be traced, it by no means follows that the trac has therapeutic value. Analysis will throw light on symptoms of general paralysis, but the disease proc is unchecked.

It is essential in treatment that the patient sufficiently intelligent to be able to coöperate, and must be willing and anxious for relief. Analysis rarely of value in persons over 50, as their habits mind are set and their repressions entrench Depressed patients suffering from the manic-depress psychosis are, as a rule, unsuitable, and analysis m precipitate suicidal tendencies. These limitations l out a very large number of patients.

ANALYSIS IN THE PSYCHOSES.

Authorities are agreed that analysis is of li value in the treatment of declared mental dise The exploration of the unconscious mind, w practicable, may explain the strange ideas of insane, but the explanation does not lead to impro ment. This is disappointing, but not surpris The essential feature in recovery after analysis is ability of the patient to readapt himself to the ne discovered facts of life, and most patients with gr mental disease are unable to do this. So far as I aware, only Jung has reported a full analysis i case of dementia præcox. The analysis elucidated symptoms, but the patient derived no benefit. is the general experience.

Opinions differ on its value in confirmed ob sional cases of long duration. Several deci successes have been recorded, and one experier analyst tells me that "really ingrained obsessions the very mischief, but from their very nature they always worth a trial." No doubt we shall all a that many obsessional cases benefit greatly by a g plain talk without formal analysis.

In manic-depressive insanity one would ex success if the analysis is undertaken in the inter between the attacks, for in this disease there is l impairment of health and the patients are often and willing to coöperate. Stoddart is evidently sang and anticipates so complete a recovery that marr and the procreation of children become justifi Yet in practice analysis is most disappointing in disorder.

One case is interesting, as the patient is a scien man, well trained in physiology and possessing acute critical mind.

He had had several recurrent attacks, some epi with excitement, and some with grave depressions suicidal impulses. At my suggestion he consulte analyst, and a month or two later he returned to Retreat in a markedly excited state, expatiating at length on his repressed ideas without any decent reserv and declaring he was cured. He derided all who dic accept the new gospel. The analyst was much conce and wrote to me that it was as if a man undergoing la tomy had jumped off the table and run about wit viscera hanging out! In a short time the patient impr again and the analysis was continued for fully three y I have since had many interesting letters from this pa who is now well enough to undertake some respo work, but he admits that he is not cured and has rec had another relapse.

CONCLUSION.

As one looks back on nearly 40 years' practice recalls many systems of treatment that have tried and found wanting. Pushed by enthusiasts, had their day and ceased to be. Is mental ana but one of the cults which flourish for a time an soon forgotten? Much that is taught, imp though it seems, rests on a slight foundation. professors speak with confidence but lack the cr faculty. They postulate an unconscious which ever be outside our comprehension, and give

onderful vitality. Changes are said to take place ithin it which can never be demonstrated. That is ardly the way of science, and much of the present bric is top-heavy. The whip of enthusiasm may ep the top spinning for a while, but the Freudian eory is inherently unstable.

Nevertheless, the new school of psychology have ade a contribution to medicine of abiding value. ey have shown the importance of subconscious ctors and have convinced us that experiences which ve apparently left no trace may still be potent and n influence our conduct unwittingly. We have rnt much about the meaning of symptoms, and the idy of our cases becomes vastly more interesting. ything which brings the physician into closer rsonal touch with his patients and requires him to ve a more minute and careful attention to their mplaints, anything that helps him to understand eir personality, must be a real contribution to the if not the science of medicine.

I will conclude with two quotations. The first is m my late friend Dr. W. H. R. Rivers, one of the arest thinkers of his time :—

"For the physician who is not content to walk in the ruts when in the presence of the greatest afflictions that befall mankind, Freud has provided a working scheme of diagnosis and therapeutics to aid him in his attempts to discover the causes of mental disease and to find means by which it can be remedied. We can be confident that the scheme as it stands before us is only the partial truth and will suffer many modifications with further research; but that it takes us some way in the direction of truth seems to me certain."

The other quotation is by Miss May Kendall, of York, of whose critical ability I have a high opinion. She was kind enough to read an early draft of this paper, and sent me the following comment. After referring to the value of modern psychology in elucidating symptoms, she goes on :—

"But that is not all. The real evangel of the new psychologists lies in the word 'sublimation.' The mental hinterland which they call the unconscious is something more than a surrounding jungle, from which poisonous growths may spread into that little clearing, the self-conscious life of the ego. It is at worst a territory which, however wild and dangerous, may to a certain extent be reclaimed and made to further the ends of our deliberate intelligence. But it is also a great reserve, which may well contain infinite sources of healing and inspiration, as well as of peril and hurt. And though it offers no smooth high road, we may divine within it many almost imperceptible paths, by which messengers may come and go, and human beings may communicate with fresh reaches of the universe."

RACTURES OF METATARSAL BONES BY INDIRECT VIOLENCE.

TH SPECIAL REFERENCE TO AVULSION FRACTURE OF THE TUBERCLE OF THE FIFTH METATARSAL.

BY ALEX. G. R. FOULERTON, O.B.E., F.R.C.S. ENG.,
CONSULTING PATHOLOGIST TO ST. MARYLEBONE HOSPITAL;
AND
GEORGE F. STEBBING, M.B., B.S. LOND.,
ASSISTANT MEDICAL OFFICER TO LAMBETH HOSPITAL.

A CERTAIN number of cases of fracture by indirect lence about the base of the fifth metatarsal bone e been recorded since the accident was first cribed by Sir Robert Jones,[1] but very little ntion has been paid to the subject in surgical -books. British writers have usually dismissed matter with a general statement that most tures of the metatarsal bones are caused by direct, rushing, violence, and an occasional reference to es's paper. The obvious reason why the particular l of fracture described by Jones was not recog-d before 1902 is that diagnosis in most of these s is possible only with radiography, a method ch had only been available in surgical practice or three years before the publication of the er. It is difficult to explain the subsequent ect of a class of fractures which must be fairly uent, and of another kind of fracture—avulsion ture of the tubercle of the fifth metatarsal bone hich also appears to be not uncommon.

he fracture described by Jones was defined as rring through the base of the bone; but from h description given, and from the radiographic trations, it appears that in the five cases recorded he paper fracture had occurred just beyond anatomical base of the bone, and in a line with anterior margin of the proximal intermetatarsal ulation, just beyond the main attachments of the ng dorsal and plantar ligaments which bind the of the fifth metatarsal firmly to the base of the th metatarsal and cuboid bones. In this situa-there is no displacement of the base of the bone, h remains in its normal position held by the nents; no crepitus is obtained. Sir Robert Jones ribed the fracture as being caused by a sudden ct of the whole weight of the body on the fifth tarsal bone, whilst the heel is off the ground and oot is inverted. He explains the mechanism thus:—

"The prominent base of the fifth metatarsal is closely d to the cuboid and to the fourth metatarsal on every side. So powerful are these ligaments that dislocation of the base is the rarest of accidents. It is obviously easier to break the bone than to dislocate it. When the heel, therefore, is off the ground, the body-weight expends itself on the fifth metatarsal, rotating it slightly inwards. The opposition of this force takes place at its base, where the strongly attached ligaments resist its displacement. A fracture occurs, therefore, exactly where one would expect it to occur, and where our skiagrams illustrate. . . . As reference to the skiagrams will show, all the lines of fracture cannot be traced quite through the bone, but there can be but little doubt but that the fracture is complete."

W. M. Brickner[2] refers to a case published by F. S. Cotton and C. S. Sylvester,[3] in which the shaft of the fifth metatarsal bone broke whilst the patient was dancing, and to five cases, published by Cotton,[4] of fracture through the base of the bone; he also records two additional cases which occurred in his own practice. In both the latter cases, one a boy, aged 12 years, and the other a woman, aged 50 years, fracture occurred apparently on sudden inward twisting of the left foot. Brickner, accepting the explanation of the mechanism of the fracture given by Sir Robert Jones, remarks that fracture may occur (1) above the base; (2) across the widest part of the base, or a little posterior to this: or (3) through the tubercle of the base. D. N. Eisendrath[5] writes :—

"A number of cases have been reported where fractures of the metatarsus occurred in soldiers after long marches, or in jumping or dancing. In the latter two instances the injury is the result of indirect violence. Such fractures may be complete or incomplete. The second left metatarsal is most frequently involved in these painful foot swellings in soldiers. In indirect violence, such as follows dancing, jumping, or sudden twists of the foot, the fifth metatarsal is most often involved."

The few instances in the literature are all of fractures through the widest part of the base, or, more distally, at the junction of the base with the shaft. Brickner, however, without quoting instances, states that the fracture may occur between the tubercle and the rest of the base of the fifth metatarsal bone.

There is, however, another fracture of the base of the fifth metatarsal bone which has to be recognised, an avulsion of the tubercle from the rest of the base. This fracture is caused, in some cases at any rate, by a sudden contraction of the *peroneus brevis* muscle and may occur, as it occurred in some of our cases, whilst the foot is off the ground. In this fracture, also, crepitus is unobtainable; but for a different reason. Instead of the fractured surfaces being held in close apposition, the torn-off tubercle is drawn backwards by the attached peroneus brevis muscle, and tilted upwards in some cases so that there is a wedge-shaped space between the separated fragments, with the base of the wedge downwards.

In some cases, as in Case 1, when the œdema which results from the fracture has subsided, the separated tubercle is found to be freely movable behind the rest of the base of the bone.

Uncomplicated Fracture of Tubercle of Fifth Metatarsal Bone.

We refer first to a series of eight cases, five of which (Nos. 4 to 8) have been treated by one of us at the Lambeth Hospital during the last 12 years; in all these radiographic examination showed that there had been a separation of the tubercle of the fifth metatarsal bone, without any other injury to the foot. In Cases 1, 3, and 4 there was satisfactory evidence that fracture occurred whilst the injured foot was off the ground, so that there could not be any question of injury by sudden impact of the body-weight on the bone. In the remaining cases there was either no evidence that the foot was off the ground at the time of the accident or else a positive history of twisting at the moment, but the radiographic appearances were like those of the three other cases. We regard them all as being probably avulsion fractures, the result of muscular action.

CASE 1, as representing the personal experience of one of us, may be given in detail. Whilst walking quietly along the street, the left foot, when off the ground, was wriggled in the boot, because of a feeling of discomfort in the little toe. Whilst the foot was still off the ground, a distinct "crack" was heard, and a sharp pain was felt, accentuated as the foot came to the ground. It was possible to limp about 400 yards with considerable pain and difficulty. On removing the boot there was a localised tenderness just over the base of the fifth metatarsal bone, and a small, tense hæmatoma developed there within half an hour. By the following day a considerable ecchymosis had appeared beneath the skin on the outer side of the foot extending from the base of the fifth metatarsal backwards to the point of the heel. The foot was rested for 48 hours after the accident; on the third day it was possible to limp about, with considerable pain at times. The hæmatoma gradually subsided, leaving a small, localised, boggy area on the outer side of the dorsum of the foot. When the general œdema of the dorsum had passed away the broken-off tubercle, held between thumb and finger, could be moved easily. The pain subsided gradually, and three months later, when the first radiograph was taken, there was still a little difficulty in walking, with occasional and sometimes severe pain.

Dr. J. O. Harvey, who kindly undertook the radiographic examination, made the following report: "The base of the fifth metatarsal bone has been fractured through with some gaping displacement. There is little evidence, there is a suggestion only, of new bone formation."

Occasional pain was experienced during the next nine months; and 12 months after the accident the tubercle remained separate from the rest of the bone, and was still movable independently when held between finger and thumb. A second set of radiographs taken at this time showed that the space between the tubercle and the rest of the bone had widened, but there was a shadow representing some material which was beginning to fill in the gap. At the time of writing, just two years after the accident, there appears to have been some kind of solid union, and all inconvenience has ceased (Figs. 1 and 2).

CASE 2, communicated to us by Dr. A. H. Williams, was that of a woman of about 30. The patient was playing tennis on a grass court, and Dr. Williams writes: "At the time of the accident she was not, apparently, making any vigorous effort. I was standing at the side of the court watching the game, when I heard a loud pop, as if a stick had been snapped. The lady subsided on the ground and complained of acute pain on the outer side of her left foot. She was at once taken to her home and on examining the foot I found a considerable swelling over the base of the fifth metatarsal bone, which was very tender and painful. No crepitus could be obtained, but X ray illumination showed clearly the nature of the case. She was playing tennis again within 12 months, and now, 18 months after the accident, does not suffer any apparent inconvenience."

CASE 3 was that of a medical practitioner, aged 30, who was playing tennis. As he put his left foot to the ground he felt that it was becoming inverted, made an effort to save himself, and experienced a sudden sharp pain on the outer side of the foot. It is important to note that the patient was quite clear that the pain of fracture did not occur when he felt that he was stumbling, but whilst he was attempting to recover himself.

Cases 4 to 8 occurred in the practice of one of at the Lambeth Hospital.

CASE 4 was that of a boy, aged 15, who, whilst runnin a 100 yards race, felt a sudden pain in the outer side of right foot, which, he was certain, was off the ground at time. In spite of the pain he was able to finish the r The accident happened in August. In the October follow whilst walking quietly about his business, he felt a sud pain in his left foot. Radiographic examination showed the tubercle on the left side had been torn off; the app ances of the fracture were identical on each side. years after the second fracture radiographs were ta for the purposes of this paper; and it appeared that t had been complete union in each metatarsal bone. A v or two after these latter radiographs had been taken, boy, after running for a short distance, felt a sharp in his right foot. It was found that the tubercle on right side had been broken off again.

CASE 5 was that of a warehouse porter, aged 28, who a sudden pain in his foot whilst in the act of lifting a h roll of cotton from the ground.

CASE 6, a woman hospital orderly, aged 40, sli whilst going upstairs. She felt considerable pain in right foot, and it was found that separation of the tub had occurred.

CASE 7, a nurse, aged 21, twisted her ankle in the w She did not experience any serious pain at the time; radiographs showed the appearance of an avulsion fract

CASE 8 was that of a wardmaid, aged 21, who had suf for some time from pain in her foot. There was no hi of injury, and, until radiographic examination show separation of the tubercle of the left fifth metatarsal. pain had been attributed to a giving way of the arch o instep.

Separation of the Tubercle with History of Pos Direct Violence.

The three following cases were instances of se tion of the tubercle with radiographic appeara exactly similar to those already described, but a history of possible direct violence.

CASE 9 was that of a man, aged 65, who was knocked by a taxicab. The patient did not think that the went over his foot, but there was extensive ecchy On radiographic examination a separation of the tu was evident.

CASE 10 was that of a workman who hurt his left and foot by falling off a motor lorry. There was sw of the foot, with localised tenderness over the base fifth metatarsal and separation of the tubercle.

CASE 11, a man, aged 54, was knocked down by a lorry. His left foot was swollen and ecchymosed; but was no abrasion of the skin, and it was not certain w the separation of the tubercle, seen on radiographic exa tion, was caused by direct violence or not.

CASE 12 is one of multiple fracture of the foot by violence in a man aged 45, whose left foot had bee over by a motor lorry. There were multiple fra of the foot, with dislocation of the second and thir and chipping of the lower end of the tibia. This c specially mentioned because radiographic exami showed that, along with other injuries, there had b separation of the tubercle of the fifth metatarsal with the radiographic appearances which are, we b characteristic of the avulsion fracture.

Fractures of the Second Metatarsal Bone.

The next case is of interest because sepa of the tubercle of the fifth metatarsal was co cated by a fracture through the second meta bone. The last two cases are quoted as instan fracture through the shaft of the second meta bone without an history of an injury of any kind

CASE 13 was that of a woman, aged 50, who slipp the step of a tramcar. She fell to the ground, breaki left humerus, and at the same time felt a sharp pain left foot. On radiographic examination it was foun there had been a fracture through the shaft of the metatarsal and a separation of the tubercle of th metatarsal bone.

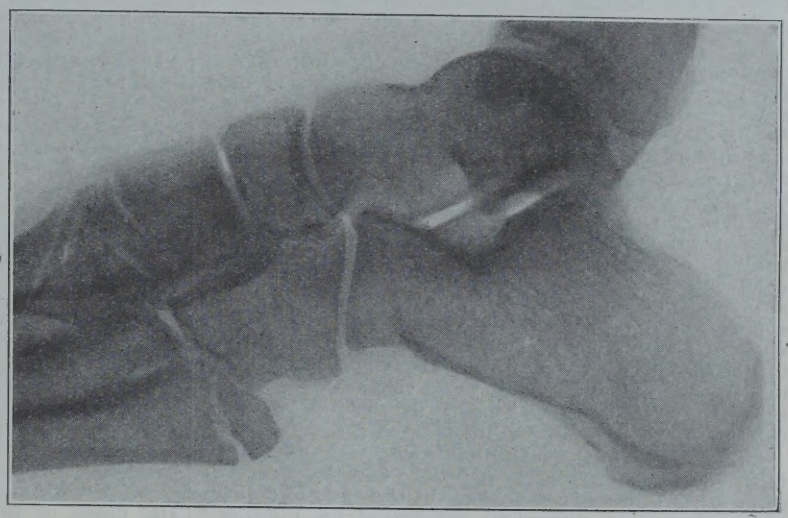
CASE 14, a young man, aged 18, was admitted in hospital complaining of pain in his foot. There was no of any sort of accident, but it was found that the shaft second metatarsal bone had been fractured.

CASE 15, a nurse, aged 21, complained of pain in her left ot after she had been on duty for some little time. Again ere was no history of an accident of any sort, and the jury to the foot was not suspected until radiographic amination showed a fracture rough the shaft of the second metarsal bone of each foot.

General Considerations.

When considering the cause of acture of the tubercle of the fifth etatarsal bone it is impossible, aving regard to Cases 1, 3, and to avoid the conclusion that in me cases the tubercle may be rn from the rest of the bone by uscular action; the only muscle at could be concerned is the *roneus brevis*. In Cases 2, 5, 6, d 7 there is either a history of, a possibility of, a twist of the ot, whilst on the ground and supting the whole body-weight. e find it difficult to imagine circmstances in which the weight the body, thrown on the outer ge of the inverted foot, could be applied as to cause a fracture the tubercle only. Under such nditions the fifth metatarsal ne would break, as Jones demonated clearly, beyond the attachnts of the plantar and dorsal laments, and not behind them. erefore we think it possible that in these cases o the tubercle is broken off by a sharp conction of the *peroneus brevis* in a sudden and oördinated muscular effort to recover from a mble or to avert a fall. When, by accident, the t comes to the ground in a faulty, inverted ition there is probably in most cases an automatic ort to correct the fault by associated action of the *onei* muscles which evert the foot. In a regularly rdinated effort with this purpose the *peronei* act ultaneously, the shorter muscle pulling on the er edge of the foot and the longer muscle on the r edge. If the short, thick *peroneus brevis* should a fraction of a second before the *peroneus longus*, "steadying" effect of the combined action of two muscles is lost, and the foot will be thrown out-

FIG. 1.



CASE 2.—Radiogram showing fracture of the tubercle of the left fifth metatarsal.

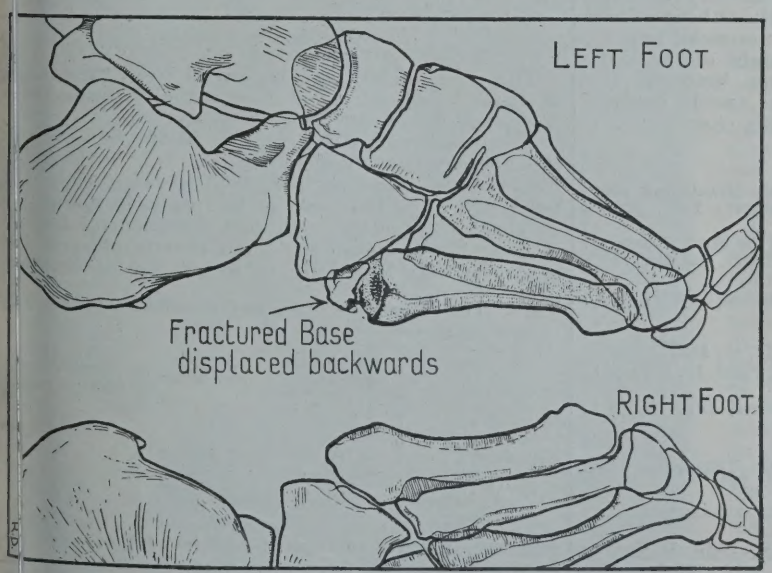
wards with a sudden jerk by the unaccustomed, independent action of the *peroneus brevis*.

Our series includes one case (9) in which it was probable that separation of the tubercle, without other injury to the bones of the foot, had been caused by direct violence, and another case (11) in which a similar fracture was associated with other injuries to the foot. In both these cases the radiographic appearances of the separated tubercle were identical with those seen in what we believe to be undoubted cases of avulsion fracture of the tubercle by muscular action.

Two cases (12 and 14) of fracture through the shaft of the second metatarsal bone without any history of external violence are specially mentioned, because they, like some of the cases of avulsion fracture, suggest an exceptional liability of the metatarsal bones to fracture by apparently slight violence. This special liability of the components of the metatarsal arch to easy fracture makes it appear that the human foot has not yet become fully habituated to the erect position of the body. This is further suggested by the fact that recorded cases show that the left foot is distinctly more liable than the right to accidents of this nature. The left foot is certainly a little less developed than the right in specialisation of function adaptive to the needs of an acquired erect position. Man may be said to be right-footed, as generally he is right-handed. Therefore functional coördination of the muscles of the left foot is the more likely to fail; the left foot is more liable to stumble than the right; and its metatarsal arch is more likely to break under the body-weight than the arch of the right foot.

When considering the apparently slight amount of force which is sufficient, in some cases, to cause a separation of the tubercle of the fifth metatarsal bone, it is interesting to note also that the tubercle may develop as a separate bone. Normally, the metatarsal bones, excepting the first, develop from two centres of ossification—a primary centre for the

FIG. 2.



1.—Twelve months after fracture, showing separation of base of fifth metatarsal bone, with atrophy of the shaft of the bone. (Drawn from a radiogram.)

body of the shaft and for the tarsal extremity or base, and a secondary centre for the distal or phalangeal extremity. But, probably under reversionary influences, the tubercle of the fifth metatarsal may present itself as a separate bone, *os vesalianum* of Pfitzner. Testut [6] had seen only a single case of this, but quotes Grüber as having come across three instances; and Pfitzner met with only one instance of the separate *os vesalianum* after an anatomical examination of more than 1000 feet. Spronk, quoted by Poirier and Charpy,[7] found *os vesalianum* in a newly born infant which showed polydactylism of the hands and feet; each foot had seven toes, the two supernumerary toes being carried by the fourth and fifth metatarsal bones. The separate *os vesalianum* in this case articulated with the cuboid bone and with the base of the fifth metatarsal. A somewhat similar anatomical variation may occur behind the bases of the first and second metatarsal bones, in the form of *ossa intermetatarsa*. The second metatarsal bone appears to be especially liable to what must be called spontaneous fracture, when the fracture occurs without any history of violence. But as the fracture in this case occurs through the thinner part of the shaft of the bone, the possibility of the existence of a separate *os intermetatarsum* is of interest only in connexion with radiographic diagnosis.

The tubercle of the fifth metatarsal being developed from what was originally one of the tarsal bones, it is interesting to note that another of the 11 true ossicles of the tarsus (*os trigonum*) recognised by Pfitzner,[8] in cases in which it has coalesced with the rest of the astragalus, is liable to separation. *Os trigonum*, when attached, is represented by the lateral tubercle on the groove in which *flexor longus hallucis* runs at the back of the astragalus, but occurs as a separate ossicle far more frequently than does *os vesalianum*. Pfitzner estimates that it remains uncoalesced in about 7 per cent. or 8 per cent. of cases. Major Brooke Churchill, R.A.M.C., has recently published [9] radiograms showing the separate bone, and also the appearances in fracture.

There is little to be said about the treatment of avulsion fracture of the tubercle of the fifth metatarsal bone. All the cases, except No. 1, were satisfactorily treated by resting the foot until union had been effected. In Case 1 the fracture was not treated at all, and somewhat prolonged disability was the result. Considering the tendency of the tubercle to be tilted backwards by the attached peroneal muscle, it is obvious that in walking the weight of the body will tend to widen the separation between the tubercle and the rest of the bone, with delayed union as a result—as happened in this case.

NORFOLK AND NORWICH HOSPITAL.—Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, recently opened an extension of this institution, which has been provided by public subscription as a memorial to the men of Norfolk and Norwich who fell in the war. The new building includes a large waiting-room, five consulting and attached examination rooms, rooms for the treatment of ear, nose and throat cases, an operating block, a recovery room for minor operations, and a casualty room.

DUODENAL ULCER IN THE FEMALE

THE CHOLECYSTODUODENAL SYNDROME.

BY D. P. D. WILKIE, M.CH. EDIN., F.R.C.S. ENG.
PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH.

WHEN we compare statistical tables of the diseases treated in our large hospitals to-day with those of 20 years ago, perhaps the most striking single difference in the present day is the frequency of duodenal ulcer. In the Royal Infirmary, Edinburgh, in 190[illegible] 24 cases of duodenal ulcer were treated, 18 by medical and 6 by surgical measures. During the same year 22 cases of perforated duodenal ulcer were dealt with in the hospital. During 1926, on the other hand, 236 cases were treated, 73 in the medical and 1[illegible] in the surgical wards. Does this difference mean that there has been an actual increase in the incidence of ulcer, or does it merely indicate that diagnosis has improved? It is notorious that we only see what we look for; hence, in part, the great disparity in the recorded incidence of different diseases in the practice of different observers in different districts or, it may be, even in the same district. In view of the number of ulcer cases treated by operation in 1926, the number of cases of perforated ulcer would be expected to show a perceptible decrease if the incidence of the disease had not varied. On the contrary, we find that in 1926 the hospital admitted 102 cases of perforated duodenal ulcer, more than four times the number of 20 years ago, and this despite the fact that, in the small provincial hospitals within the area served by the Royal Infirmary, operations for perforated duodenal ulcer are now quite common. (Table I.)

TABLE I.—*Incidence of Duodenal Ulcer in the Royal Infirmary, Edinburgh.*

M. = male. F. = female.

The only inference to be drawn from these figures is that duodenal ulcer has actually increased in frequency during the past 20 years.

There is apparently a fairly widespread opinion in this country that duodenal ulcer is rare in the female. Experienced surgeons have told me that they could not recall more than one or two cases in many years of surgical practice. In my experience, duodenal ulcer is much commoner than gastric ulcer in both sexes, so that I venture to record my observations,

TABLE II.—*Incidence of Ulcer Operated on 1921 to 19[illegible]*

—	Duodenal ulcer alone.	Gastric ulcer alone.	Coincident gastric and duodenal ulcer
Males	234	22	33
Females	76	30	18

and with them a statement of what I believe to be a frequent cause of failure to diagnose this disease in the female. Data are now available which point very clearly to the ulceration being infective and, indeed, streptococcal in origin, and it is not unreasonable to suppose that a streptococcus with a special acquired affinity for the duodenal wall is prevalent, and accounts for the increasing frequency of the condition.

Incidence of Ulcer.

An analysis of ulcer cases erated on by me during the st six years shows that, out a total of 413 cases, there were cases of duodenal ulcer in the nale. In 18 of the latter there as a coincident gastric ulcer. able II.)

Duodenal ulcer occurs in the nale, as in the male, at all es. My youngest patient was irl of 16, whilst three patients re 70 or over. The average e at the time of operation was . It occurs both in the thin henic type of female and, per- ps even more often, in the ut, well-favoured type. It urs with almost equal fre- ency in hospital and private ctice (51 in hospital, 43 in vate practice). There would pear to be an undoubted here- ary tendency to ulcer, par- ularly in females. I have had deal with two families in each which three sisters have been rated on for duodenal ulcer. re than 80 per cent. of the ients were non-smokers.

Symptomatology.

n many cases a typical his- y was given: periodic attacks ndigestion with hunger-pain, relief from food, long iods of freedom from symptoms in the early stage, more constant trouble as time went on, but in quite a large proportion (35 per cent.) the history was not classical. Flatulence was often the chief complaint; associated with this were attacks of acute pain, apparently without any definite relation to food, occasionally associated with vomiting and sometimes followed by a faint tinge of yellow in the skin. At such times the patient complained of much acidity and heartburn. On at least ten occasions I have operated on a diagnosis of cholecystitis, only to find a normal gall-bladder and a typical duodenal ulcer.

Gradually we have come to recognise a clinical picture which I have termed the *cholecystoduodenal syndrome*. The patient is usually somewhat stout, complains of "wind" and attacks of pain in the epigastric region to the right of the midline. She is uncertain of the relation of the pain to the taking of food, but has usually lived for some time on a restricted diet, avoiding potatoes and all "heavy" articles of diet. She describes attacks of pain lasting for a few hours, very suggestive of biliary colic. On careful questioning, however, these attacks are found to be less severe than true colic. When questioned as to jaundice, she will state that friends have remarked on a yellowish tint in her skin at these times (duodenitis with catarrh). Leading questions will elicit that at some time or other, and almost always on more than one occasion, she has had an attack of indigestion, lasting for a few weeks, of almost typical duodenal type.

Whether it be that the average female is less observant, or is merely more tolerant of a recurrent pain than the male, or whether the pylorus in the female does not react so readily by recurring spasm to duodenal irritation, is uncertain. It is undoubtedly true, however, that a somewhat vague and indefinite history of flatulence and

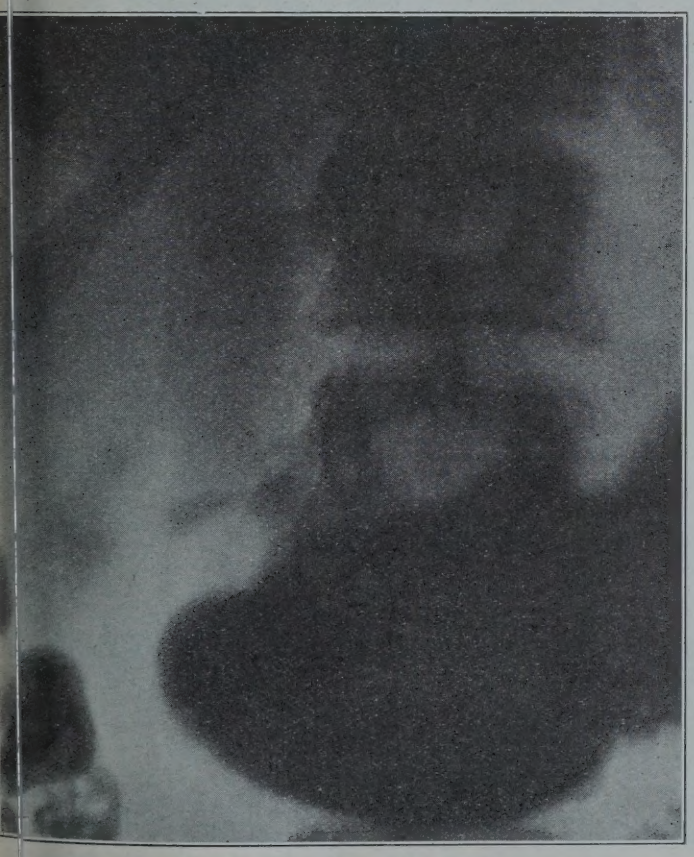
FIG. 2.



case as in Fig. 1 two hours after fatty meal and immediately after barium meal. Gall-bladder partly emptied and pronounced deformity of duodenal cap.

FIG. 3.

Faint gall-bladder shadow and deformity of duodenal cap. Early cholecystitis and duodenal ulcer.

irregular pain is the common story in the female. The most probable explanation of the absence of the typical hunger-pain in the female is the prevalence of the habit, among those engaged in household duties, of taking food between regular meal-times and thus of anticipating the onset of hunger-pain. The male, with fixed hours for work, has longer fasts and less opportunity of warding off the hunger-pain. Whatever the cause, it is a fact of experience that in many cases of duodenal ulcer in the female the classical history is not volunteered, and can only be elicited with difficulty, and then imperfectly. In the majority of my cases the patients had suffered from dyspeptic symptoms for many years and, whilst a tentative diagnosis of cholecystitis had frequently been made, their pseudocolic attacks had never been considered sufficiently severe or disabling to warrant surgical interference.

Accurate Diagnosis by Cholecystography.

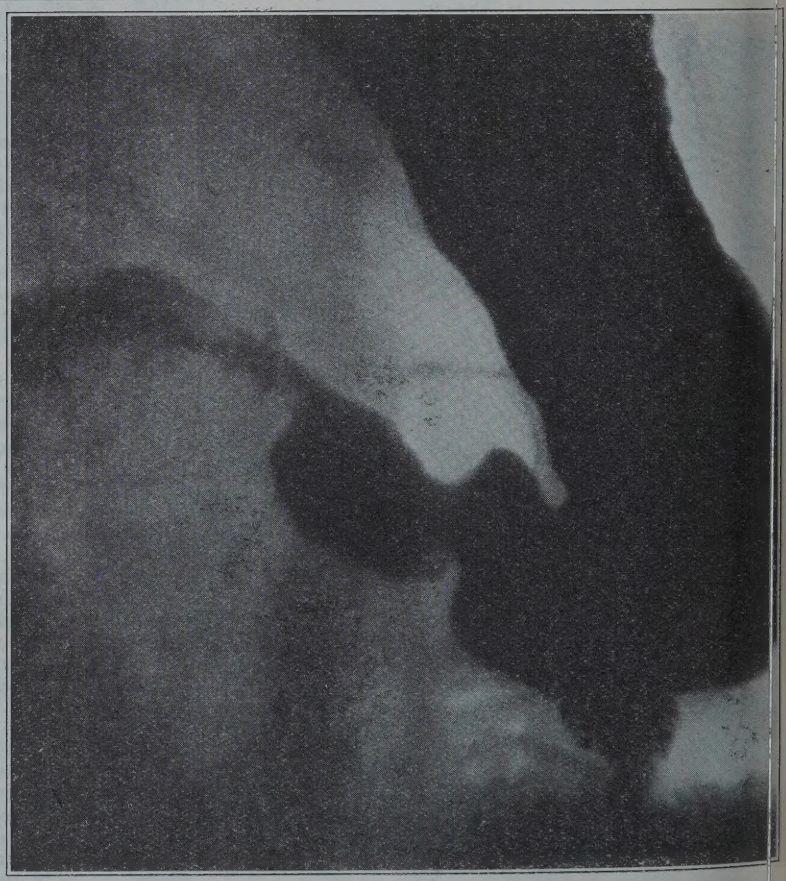
During the past year I have had to deal with five cases, admitted to hospital with a provisional diagnosis of cholecystitis and gall-stones, in which preliminary investigation by cholecystography has led to a positiv diagnosis of duodenal ulcer and norm gall-bladder. The patients have all bee females, and the histories in all were ce tainly more suggestive of gall-bladd than of duodenal mischief.

The technique which we now follo at the suggestion of Dr. Woodbu Morison, is important. On the night admission the patient is given a dose liquorice powder. The following day preliminary X ray photograph is take That evening at 9 o'clock an intraveno injection of 3 g. of sodium tetraiod phenolphthalein is given in 40 c.cm. distilled water. At 9 o'clock the follo ing morning an X ray (with Buc diaphragm) is taken. The patient is th given a barium meal, and the stoma and duodenum observed on the scre and a second photograph taken. 1 P.M. a fatty meal is given, and at 3 P. the final X ray is taken.

In the five cases referred to the ga bladder gave a normal cholecystogra and the barium meal in each instan showed an unmistakable deformity the duodenal cap. (Figs. 1 and 2.) operation, one or more duodenal ulc were found in each case, and the ga bladder was normal. In a sixth case t cholecystogram showed a shrunken ga bladder with stones, as had be expected, but in addition a duoden ulcer. At operation both conditio were dealt with successfully.

I have no hesitation in stating that

FIG. 4.



Same case as in Fig. 3. Stomach allowed to fall over to left, demonstrating duodenal ulcer with stenosis.

e combined cholecystography and barium meal test scribed above we have a most valuable diagnostic d in female patients presenting the cholecysto-odenal syndrome.

Operative Treatment.

I have found that some form of conservative short-cuiting operation has been uniformly successful. here does not appear to be the same tendency to ptic ulcer of the jejunum in the female as in the ale. The relatively mobile duodenum in the female akes a gastro-duodenostomy (Eiselsberg) an easy d safe operation, and I have latterly preferred this a Finney's operation to gastro-jejunostomy as ing more physiological. In the 76 cases in which gastric ulcer was present, posterior gastro-enteros-my was performed in 47 cases, gastro-duodenostomy 20, Finney's operation in 4, and excision with loroplasty in 5 cases.

When a coincident gastric ulcer is present, as it was 18 out of the 94 cases here recorded, the treatment ust vary according to the local condition and the e of the patient. When a chronic penetrating gastric er was present, excision of the ulcer followed by stro-enterostomy was the operation of choice. For all active gastric ulcer, high on the lesser curvature, e cautery was used. In six of my patients, all erly, an hour-glass contraction of the stomach, e to an old and practically healed gastric ulcer, s present; a gastro-gastrostomy followed by stro-enterostomy in the lower sac (five cases), or ouble gastro-enterostomy and a lateral anastomosis ween the limbs of the jejunal loop (one case) gave npletely satisfactory results. In nine cases chole-titis with gall-stones was found, associated with e duodenal ulcer. (Figs. 3 and 4.) In six of these olecystectomy, in two a cholecystostomy, and in e a cholecystectomy and a choledochostomy were formed. The appendix was diseased and was moved in approximately one-third of the cases. I one case, besides the duodenal ulcer, an active stric ulcer, a subacute cholecystitis, and a pro-lirative chronic appendicitis were present. The gall-bladder, appendix, and gastric ulcer were excised, a l a gastro-duodenostomy performed.

have yet to be convinced of the necessity for ensive resection for simple ulcer of either stomach duodenum or both.

Summary.

. Duodenal ulcer appears to be a much commoner ease now than it was 20 years ago. 2. Duodenal er is a common disease in the female, more so n gastric ulcer. 3. The typical history is much frequently given than in the male, hunger-pain n being absent. 4. The "catch meals" of the sewife are probably responsible for the indefinite ure. 5. Under the term cholecystoduodenal drome a clinical picture, often confused with that holecystitis, is described. 6. Operative treatment conservative lines is recommended.

ALKALI TREATMENT IN DIPHTHERIA AND SCARLET FEVER.

By B. A. PETERS, M.D., D.P.H. CAMB.,

MI CAL OFFICER, HAM GREEN HOSPITAL AND SANATORIUM; CTURER IN INFECTIOUS DISEASES, UNIVERSITY OF BRISTOL.

THE present writer [1] showed, in 1918, that an ac osis (a reduced alkali reserve), associated with ke nuria, occurred in the more toxic cases of di theria, and that the administration of alkalies te led to prevent the pernicious vomiting and ci latory failure which may occur in the second w k of the disease. Since then the routine treat-m t of all cases of diphtheria in this hospital has in ded the administration of 30 g. sodium bicar-bo ate, 5 g. potassium bicarbonate, and 7 g. calcium ca onate in four-hourly doses, until the morning u e is alkaline to litmus, which takes three or four days. For younger children the dose is halved. My colleague, F. J. Hector,[2] has confirmed these observations and shows that the reduced alkaline reserve is associated with some defect in carbohydrate metabolism.

In a report on wound shock,[3] it was very clearly demonstrated that experimentally produced "acidosis" will not in itself cause any appreciable symptoms, even when the alkali reserve is reduced to what is probably a lower level than would ever occur naturally. The original explanation of the undoubted benefit derived from these measures is therefore untenable. Richet [4] and others have shown that anaphylactic shock may be prevented by administering saline with the second dose of serum. Moore [5] considered that in a severe toxic state, such as cholera, the crystalloid-colloid balance is upset, and that "electrolytes are wanted to combine with circulating toxic colloids and tissue colloids and to prevent these linking on to each other." Crystalloids are also necessary to tug the toxic colloid through the excreting channels. This is probably the explanation of the advantage of drenching the patient with basic salts. It is important, therefore, to give large doses of these salts in the early stage of disease, to prevent fixation of the toxin to the tissues until the antitoxin has had time to do its work. It is also vitally important to discontinue their administration when the acute stage is over, as an alkalosis may produce an anoxæmia [6] or may damage an already partly poisoned heart.[7] It is interesting to note the craving of febrile children for fruit and their complete distaste for other foods. This may be an instinctive attempt to make up a deficient alkali reserve.

In this communication I attempt to assess the clinical value of these measures from a study of records extending over 18 years. Although we have careful records of 10,000 cases treated with and without alkalis, it is impossible to bring forward incontrovertible statistics because a new and immeasurable factor was introduced—viz., the outbreak in 1920 of a much more severe type of disease which is only now reverting to the former type after a widespread and virulent epidemic. This type was characterised by great swelling of the throat and neck, appearing within 24 hours of onset; by delayed formation of membrane, causing great difficulty in diagnosis, and in many cases by the death of the patient from overwhelming toxæmia within three days. During this time 20 per cent. of the nursing staff were very severely attacked, one nurse dying on the fourth day, although 40,000 units of antitoxin were administered within six hours of the onset of symptoms. This was before Schick methods were used. The death-rate, therefore, is no guide. In fact, the alkali-treated group show a death-rate of 6·4 per cent., compared to 5·6 per cent. for the other group.

I have therefore attempted to arrive at some conclusion by comparing those in each group who showed the cardiac vomiting syndrome.

The Cardiac Vomiting Syndrome.

Between 1903 and 1917 4894 cases of diphtheria were treated in this hospital without alkalis; 148 cases (3 per cent.) showed the cardiac vomiting syndrome. Of these, 102 died (one survived a month, only to die of diaphragm paralysis), 46 recovered—i.e., more than two-thirds died, or 2·1 per cent. of the whole group untreated by alkalis.

In the second group, from 1918 to 1927, 5880 cases were treated by alkalis. Of these, 65, or 1·1 per cent., died with cardiac vomiting symptoms (i.e., half the former number), 148 showed some vomiting with heart weakness, but eventually recovered, while ten of the vomiting cases recovered from the vomiting stage only to expire of diaphragm paralysis. This increase of paralytic cases was also noted after the introduction of antitoxin, and the explanation is probably similar—i.e., that a large proportion of the severe cases lived long enough to develop these symptoms. Therefore, although we are dealing with a much more severe type of disease, with a higher

percentage of vomiting cases (3·8), more than two-thirds eventually recovered, as against one-third in the former group. If the same type of disease had persisted throughout, the figures would have been much more favourable to the alkali-treated group, as in 1918–20 (before the type of disease changed) only six fatal vomiting cases occurred among 1237 patients (0·5 per cent.)—i.e., a quarter of our former steady percentage (2·1).

There is also a striking clinical difference in the two groups. Without alkalis the vomiting is very frequent, is quite uncontrollable in two-thirds of the cases, and ends with bilious and finally with "coffee-ground" material. If vomiting starts in the alkali-treated cases, it is not nearly so frequent or distressing, the vomit never assumes the coffee-ground appearance, and less than one-third die.

Scarlet Fever.

In recent publications by Osman [8] and Berry [9] it is stated that alkali treatment in scarlet fever prevents nephritis and possibly rheumatism and endocarditis. These observations were anticipated by my former colleague, R. Thomas,[10] in 1919, working in this hospital. He stated that "acidosis aids in determining the onset of this complication (i.e., nephritis), and that early administration of soda may reduce its incidence." Since 1918 alkalis have been administered in scarlet fever in the same doses as for diphtheria during the acute stage only, usually for about a week, as Thomas showed that an acidosis with ketonuria was then present.

The experience of this hospital, extending over 17 years, is given in the two succeeding tables.

1926 ..	505	10	43	2
1927 .. (9 months)	420	2	20	6
Totals	4290	86	94	33
Percentage attack rate of complications ..		2·0	2·2	0·77

It will be seen that our experience does not bear out Osman's contention, as there is no significant difference in the onset of complications in the two groups. It will also be seen that different structures appear to be singled out for an attack in different years, so that unless observation is extended over a long period, as well as over a large number of cases, very erroneous conclusions may be drawn. Osman continues the administration of large doses of alkalis throughout convalescence. There is no evidence of any shortage of alkalis in the tissues at this stage, especially if, as in this hospital, the patient is given a vegetarian diet, rich in bases, during the first thr weeks of the illness. We only give alkalis whe we have found definite evidence of a shortage of th alkali reserve—i.e., during the acute stage.

He notes four cases of nephritis in his series 600 cases, one ending in death. In our first grou (treated without alkalis) two fatal cases of nephrit occurred out of 3648 cases. In the second group, treat with alkalis, there was no fatal case of nephritis.

It is well to remember the warning in the Medic Research Committee's Report [3]: "An abnormal high alkali reserve can be as rationally consider undesirable as can a low one; possibly more s since the only method by which the normal level c be rapidly restored is by depression of tissue oxidatio which may give rise to other and more harmf products than fixed acids."

THE RÔLE OF CARBON DIOXIDE

IN THE GROWTH OF NORMAL AND TUMOUR CELLS.

BY J. C. MOTTRAM, M.B. LOND., M.R.C.S. EN
DIRECTOR, RESEARCH DEPARTMENT, RADIUM INSTITUTE, LONDON.

THE similarity between the behaviour of norm cells cultured in vitro and of cancer cells growi in the body has not been sufficiently stressed. F instance, kidney cells from an adult rat, when cultur in vitro, exhibit three important cancerous characte (1) they migrate out into the medium; (2) th exhibit de-differentiation; (3) they undergo abunda mitotic cell division. Results obtained with in vi cultures [1] suggested that in normal tissues th tendencies of normal cells were held in check inhibitory factors, and that in the repair followi injury inhibition was temporarily lost, whilst cancer the loss was sustained. Thus cancer would due to a change in the cell's environment, in whi an inhibitory factor is destroyed, rather than one which a stimulating factor is added. It is importa therefore, to discover what are the environmen factors common to cells undergoing cancerous char in the body and cells growing in vitro which sh cancer-like behaviour.

Researches have shown that in the body the ce environment is remarkably constant, so that it h been said that the chief function of the body is ensure a constant environment for its cells, to prot them from the wide environmental variations which the animal as a whole is exposed. This co stancy is largely controlled by the circulation of t blood, which regulates the temperature, the supp of food and oxygen, the carrying-away of wa products and carbon dioxide, the hydrogen-i concentration, &c. The question then arises whet a change in blood-supply is the common ætiologi factor present in all the various pre-cancerous co ditions, such as those which follow chronic irritati radiation, tarring, &c. The numerous pre-cancero conditions occurring in man, or as the result experiments in animals, have been described detail, and form a vast literature, in which there much evidence of a decreased blood-supply. Su descriptions as "obliterating inflammation of t blood-vessels," "perivascular sclerosis," "localis arterio-sclerosis," "hyperplasia of the endothe cells of the capillaries after X rays and radiu frequently recur. If, therefore, an altered blo supply is a common ætiological factor, it would b diminished and not an increased supply. A diminish

lood-supply leads to an interference with the gaseous nsions of the cells' environment which the body at pains to regulate precisely. The following xperiments have, therefore, been made to discover ow normal cells behave when grown in vitro under arious gaseous tensions.

Experimental Details.

Exposures of in vitro cultures to various gases were made McIntosh-Fildes anaerobic jars. For the cultures, hollow-ound slides were used, having grooves cut on either side as to provide free communication with the outside after e cover-glass had been sealed on with paraffin wax. The ltures were placed in Petri dishes, on blotting paper oistened with Locke's solution. The gases used were rogen, oxygen, and carbon dioxide obtained from linders, and hydrogen from a Kipp's apparatus. The aerobic jar was connected with a mercury manometer measure the gaseous pressures, which were controlled by air pump.

Rat kidney cells, rat fibroblasts, and Jensen's rat sarcoma ls were used for culturing. Migration of the cells into culture medium (chicken plasma or serum) was used as measure of vital activity.

Experiments with Oxygen.

No extrusion of cells was observed in the complete sence of oxygen.

This was obtained either by combining the oxygen with drogen in the usual way, so that finally the jar was filled h a mixture of nitrogen and hydrogen; or by first half-ng the jar with carbon dioxide and then washing out the bon dioxide with nitrogen, until the gas coming away e no precipitate on passing through barium hydrate. fore incubation, and in all the experiments with oxygen, mm. of carbon dioxide were added to the contents he jar, so as to lower the pH value of the plasma. Con-trations of oxygen below that of the air were obtained exhausting the jar to a suitable level and filling with rogen.

Table I. gives the results obtained.

TABLE I.

Oxygen pressures in mm.	Kidney cells.	Fibroblasts.	Sarcoma cells.

600	+	+	+

−, No extrusion of cells. +, Extrusion of cells. V.sl., Very slight. Sl., Slight.

There is no difference between the behaviour of kidney cells and that of fibroblasts. In contrast, sarcoma cells exhibit evidence of activity in much lower concentrations of oxygen, though their activity is reduced at low tensions and absent under complete anaerobiosis. Those cells not showing activity under anaerobiosis or low oxygen tensions were not dead, for if favourable gaseous conditions were subsequently applied, extrusion of cells took place, confirming Otomoto's findings.[2]

Experiments with Carbon Dioxide.

Mixtures of carbon dioxide were obtained by exhausting the jar and then filling up with carbon dioxide. Experiments showed that the act of exhausting the jar, even to a few mm., does not prevent the

from subsequently migrating out into the medium in normal manner. Table II. gives the results.

Extrusion, therefore, can occur at carbon dioxide tensions far above the 40 mm. naturally found in the tissues. There is no difference in behaviour between fibroblasts and sarcoma cells, but kidney cells do not migrate so readily at the higher and lower concentrations. The absence of migration at 400 and 600 mm. is not due to an absence of oxygen.

pH Values.

Side by side with these experiments, measurements of the pH values of serum in equilibrium with varying tensions of carbon dioxide were made in Prof. E. C. Dodds's laboratories at the Middlesex Hospital by Mr. N. F. Maclagan, to both of whom I am indebted for the following results. Glass electrodes were used, as described by Kerridge.[3] Tubes of serum were left overnight at 35° C. in the jars filled with the mixtures of gases. Tubes of liquid paraffin were also placed in the jars. When the jars were opened the paraffin was at once poured on the serum and the tube tightly corked. The serum was subsequently manipulated under liquid paraffin to prevent the escape of carbon dioxide.

It is seen that the tolerance of these cells towards oxygen and carbon dioxide is very different. In the case of carbon dioxide there is an upper limit, whereas for oxygen there is a lower limit. For carbon dioxide there is a tension for optimum cell activity, as this is depressed at low tensions as well as at high. Since variations in blood-supply, by altering the carbon dioxide tension on either side of this optimum, could thus control cell activity, the question arises whether there is any evidence for such control.

Those who take a wide biological view will admit that an acid environment due to carbon dioxide is often an important factor in the manifestation of growth. Loeb[4] has shown that the segmentation of unfertilised ova can be started by subjecting them to a number of chemical agents, of which carbon dioxide and the mono-basic fatty acids are especially effective. It is known that carbon dioxide penetrates living cells more easily than all other substances, not excluding water, and that the permeability of cells so penetrated is greatly altered, so that oxidation is increased and the metabolic rate raised. Carbon dioxide has also a controlling influence in the action of many enzymes, chiefly through alteration of pH values. In plants growth, the building of carbohydrates and many other vital processes vary with the hydrogen-ion concentration in the tissues produced by varying accumulations of carbon dioxide.

Pearstall and Priestley[5] have shown that in plants the cambium layer lies across a steep gradient of pH 3·0 to 6·5, and conclude that growing cells are situate when the pH value is that of the iso-electric points of the principal plant proteins, which is about 4·4. Pauli[6] gives the iso-electric points for a number of animal proteins: albumin, 4·7; casein, 4·6; hæmoglobin, 6·75; and serum globulin, 2·66. It is to be noted that these are all on the acid side. The iso-electric points of the proteins of living cells are not known, so we are thus unable to predict the pH value most favourable to growth in the case of animal cells. Much recent research has been done on the pH value of the interior of living cells.[7] This appears to be remarkably constant in the neighbourhood of pH 5 to 6·5, and hydrogen-ions in the cell's environment are much more effective in altering this than are OH ions. During mitosis, wide excursions of pH value occur.[7] It is also to be noted that the rapid growth of cells seen in tumours and in embryos is associated with a low pH value due to the presence

of lactic acid as well as carbon dioxide.[8 9] The metabolic gradients observed by Child,[10] which he has shown to be intimately concerned with dominance in growth and regeneration, must also condition a carbon dioxide gradient.

Lastly, not only do we find evidence of the origin of carcinoma in situations of diminished blood-supply, but its spread through the body, such as lymphatic permeation, and growth in lymphatic glands, spleen, liver, and bone-marrow, suggests that situations distant from the circulation are favoured. Tumours have not been produced in animals by direct treatment with acids, but Smith[11] has shown that the plant tumours produced by bacteria are reactions to the local production of increased acidity. He has produced tumours by acetic acid and by agents which cause local semi-asphyxiation. It would seem, therefore, that there is evidence that an environment of high carbon dioxide tension encourages cells to anabolise, de-differentiate, and grow, whilst an abundance of oxygen and an absence of carbon dioxide has a reverse effect.

Warburg[12] likewise postulates a chronic anoxæmia as an ætiological factor in cancer, but from a different standpoint. He lays stress on a deficient oxygen supply. He has shown that tumour cells differ from normal cells in that they hydrolise glucose to lactic acid, both in the presence and in the absence of oxygen, much more actively than normal cells, and thus obtain energy for growth under anaerobic conditions.

In our experiments no evidence of cellular activit was obtained in the complete absence of oxygen, eve when glucose was added. On the other hand, Wind obtained growth under anaerobic conditions, usin Rous sarcoma; if, however, the medium was mad glucose-free by dialysis, growth did not occur. Neve theless, our experiments support Warburg's finding in that Jensen's rat sarcoma presents activity at muc lower tensions of oxygen than do normal cells.

No matter whether increased carbon dioxid tension or diminished oxygen tension or both pla a part in the ætiology of cancer, it is evident that diminished blood-supply must result in both, and th part played by carbon dioxide may be very importan

Clinical and Laboratory Notes.

A NOTE ON THE INDUCTION OF LABOUR IN PELVIC DEFORMITY AND MATERNAL ILLNESS AND ON THE TREATMENT OF ANTEPARTUM HÆMORRHAGE.

BY ETHEL M. TOWNEND, M.D. LOND.,
MEDICAL OFFICER TO THE MUNICIPAL MATERNITY HOME, HULL.

Dr. Henry Jellett in a recent article deprecates the too frequent use of Cæsarean section in the less severe forms of obstetric abnormality.

At the Hull Municipal Maternity Hospital all the patients are kept under observation during pregnancy and malformations corrected by external manipulation where possible. In some cases it is found that even with abdominal pressure the head will just not enter the brim at about the thirty-seventh week. These cases of slight flattening form, according to Whitridge Williams, 95 per cent. of all contracted pelves, and they will not permit a full-term head to pass. Induction of labour is, in my opinion, the best treatment for this class, and also for cases where the mother suffers from albuminuria or decompensation.

Much criticism has been advanced against induction on the ground that a premature child is difficult to rear, but it will be seen from the statistics given below that, where disproportion is the only abnormality, the mother healthy, and the presentation normal, over 90 per cent. of the infants are still alive and well, their ages ranging from three months to four years. Moreover, 100 per cent. of the mothers were discharged alive and with a sound uterus and abdominal wall. Adverse critics also maintain that, if left to nature, some of the cases would perhaps succeed in delivering themselves in spite of apparent disproportion. Even if this be so, it is surely better to err by inducing labour a little prematurely while the risk to mother and infant is almost nil than to leave her to face a protracted labour, which may require Cæsarean section in the end. Even if delivery can be effected by forceps the injury to the mother's genital tract and the fœtal skull are often considerable, especially when the arrest is at the brim.

Induction has been found very useful in severe cardiac decompensation, where the elimination of prolonged labour, shock, and anæsthesia is partic larly important.

The Method of Induction.

Bougies were used in the earlier cases, the avera time required between introduction and delive being five days. I next used Prof. C. G. Lowr toy balloon, the average time then being two and half days. Jacques's œsophageal bougie is now use and reduces the time to 18 hours. Another advanta of this method is that no ladder is left in the vagi up which infection may pass into the uterus. pituitrin has been used, because its effect in a individual case cannot be foretold. The detail treatment of these cases is as follows:—

Where time permits, castor oil, quinine, and hot douc are given on alternate days for three days, as advised Dr. T. W. Eden. In some cases this alone is sufficient make the head engage. Moulding will then take place, a the case is left without further treatment. No quinine given if the mother is suffering from heart disease. If head remains above the brim a hypodermic injection Burroughs, Wellcome and Co.'s tabloid hypod. hyosc co. B. is given, and half an hour later the vagina swabb out and an iodine douche given. A little open ether sometimes required in primiparæ, but not often. T boiled Jaques's œsophageal bougie is now held in the gloved hand, and the patient placed in the lithoto position. The end of the tube is guided into the external by two fingers of the right hand placed in the vagina. Af the use of quinine the os is always patent enough to all the tube to pass. No vulcellum forceps are required desirable. By gentle pressure the tube glides into uterus, care being taken that the last portion passes throu the internal os. The delivery is now left to nature, and tube does not cause any pain or discomfort. It is, of cou essential that as much care be exercised to ensure asep as would be taken if the abdomen were to be opened. No c of pyrexia occurred in the series.

Antepartum Hæmorrhage.

I have had 68 cases of antepartum hæmorrha in 3400 deliveries. Internal version was perform

times with three maternal deaths; two of the tal cases were pulseless when admitted; 20 of the fants were born alive. In two cases in which I led to turn the fœtus I found after delivery (by ceps) that it was in a state of rigor mortis, the ibs were quite stiff, and the mouth could not be ened. I should be interested to know if this ndition has been frequently observed. Both mothers re in a satisfactory condition.

I wish to thank Dr. W. Allen Daley, the medical icer of health, for permission to publish these notes, d Dr. Susan H. Gilchrist, assistant medical officer maternity and child welfare, for obtaining the er-histories of the infants.

A NOTE ON THE LESS COMMON CAUSES OF OBSTRUCTIVE JAUNDICE.

BY A. RENDLE SHORT, M.D., B.SC. LOND., F.R.C.S. ENG.,
SURGEON TO THE BRISTOL ROYAL INFIRMARY.

SINCE the van den Bergh test and cholecystography vided a means of clinical distinction between onic jaundice due to obstruction of the bile passages jaundice due to other causes, it has become clear t a group of cases exists in which there is obstruc- of the bile passages without either gall-stones, ignant new growth, or cirrhosis of the head of the creas. Patients belonging to this group are ally young women, and the jaundice is persistent, pain is not conspicuous. Three examples of this ical syndrome have recently come under my care; were verified by operation, and the cause was d and removed, the jaundice disappearing in case. Two had enlarged lymphatic glands sing on the common bile-duct; these were rculous in one case and simple inflammatory he other. The third showed a condition which be called vateritis.

Case Reports.

SE 1. *Obstructive jaundice due to tuberculous lymphatic ds.*—Female aged 25. History of jaundice for three ths, running an up-and-down course, the stools some- s clay-coloured and sometimes showing a little bile, rine usually bile-stained, but occasionally nearly clear. rtain amount of colic, like mild attacks of biliary colic, not conspicuous. Diarrhœa at first, and occasional ting. Had had part of clavicle removed for tubercle. and spleen both palpable and enlarged. Gall-bladder elt.

eration showed a small deeply situated gall-bladder, large tuberculous glands in a chain running alongside pressing on the common bile-duct. Glands removed; luct drained. Closed in a week.

e jaundice cleared up. The patient died two years , after a long illness, of which no details are lable, but without jaundice, probably abdominal rculosis.

SE 2. *Obstructive jaundice due to inflammation of hatic glands.*—Female aged 27. History of jaundice ur months, with a week almost free in the middle of lness. Diagnosed at first as ordinary catarrhal jaundice. ever, pain insignificant, except just at the beginning. deeply bile-stained; stools pale. Van den Bergh: —delayed biphasic. Cholecystography: very faint w of gall-bladder, normally shaped.

operation, gall-bladder was not enlarged; no stones no adhesions or thickening. All along the left side of mmon bile-duct were large, soft, red lymphatic glands, as large as walnuts. Several of these were removed. all-bladder and ducts were not opened.

e jaundice cleared up in a week, bile returned e stools, and the urine became normal. The toms have not returned. The glands showed oscopically a simple inflammatory swelling, ably due to the infection that was responsible he original catarrhal jaundice.

CASE 3. *Obstructive jaundice due to vateritis.*—Female aged 28. Jaundice started in September, 1926. Some abdominal pain, but not much. Bowels regular, motions pale. Urine bile-stained. Pulse and temperature normal throughout. No pain since February. Lost 10 lb. in weight. Slight resistance over gall-bladder, suggesting enlargement. Cholecystography: gall-bladder does not fill. Van den Bergh: direct—rapid biphasic.

At operation, in May, 1927, gall-bladder distended, full of "white bile." Ducts distended. Common duct opened, no stone present. Duodenum opened; no stone in ampulla of Vater, though it was thoroughly explored; ampulla very swollen and purple in colour. Common bile-duct distended down to the ampulla; probe arrested there. No obvious cause for the condition of the ampulla. Internal drainage established by a drainage-tube from the common bile-duct to the duodenum through the ampulla. Gall-bladder also drained for a few days.

The jaundice rapidly cleared up, and bile returned to the stools. The internal drain was passed some weeks later.

THE ERADICATION OF BILHARZIASIS: A SUCCESSFUL ATTEMPT IN AN ENDEMIC AREA.

BY M. KHALIL, M.D. BRUX., PH.D., M.R.C.P. LOND.,
PROFESSOR OF PARASITOLOGY, FACULTY OF MEDICINE, CAIRO.

AN attack on trematode infections through their intermediate host, the snail, has been attempted in various countries, especially in the Far East. Many chemicals have been advocated, but the most potent are copper compounds,[1] which were first tried on the actual snail-carriers of bilharzia in 1921.[2] An exhaustive study of the effect of copper sulphate on agriculture in Egypt was carried out prior to the present attempt,[3] which was undertaken, at the beginning of April, 1927, at an Egyptian oasis *Dakhla*, 450 kilometres from the Nile. It is reached partly by railway and partly by desert motor-cars, so that its situation ensured a complete isolation rarely available elsewhere.

Forty per cent. of the inhabitants of the village submitted their excreta for microscopical examination; 63·5 per cent. were found infected with *Schistosoma hæmatobium; S. mansoni* was totally absent. The main stream of the village, originating from an artesian well, was found to contain large numbers of bullinus snails. Copper sulphate was continuously added to the stream for four days and nights by a specially improvised apparatus. The dilution aimed at was five parts of copper sulphate to a million of water. At the end of the experiment all bullinus snails were dead. The water flowing through the stream was calculated at 79·30 cubic metres per hour, and 38·5 kg. of copper sulphate were used.

After six months the area was visited again and carefully surveyed. No living bullinus snails could be found, in great contrast to their abundance before the experiment. The six months interval was the hottest period of the year, and the most favourable time for the propagation of mollusca. The area will be surveyed at intervals, and if the result remains as good, similar experiments will be tried in the Nile Valley itself. No deleterious effects were observed on the vegetations, animals, or man as a result of the experiment.

The details of the trial and the description of the apparatus especially devised for automatically delivering a constant dilution of copper sulphate will be the subject of another publication.

I am indebted to Dr. M. Helmi, of the Research Section, Public Health Laboratories, for his valuable coöperation during that trial.

Medical Societies.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

AT a meeting of this Society held on Nov. 18th, Dr. JOHN COWAN, the President, in the chair, Mr. ROY YOUNG opened a discussion on the

DIAGNOSIS OF SURGICAL DISEASES OF THE KIDNEY.

In suspected urinary trouble, he said, routine examination entailed: (1) A complete history and a thorough examination of the patient, with blood pressure readings. (2) Chemical and microscopic examination of the urine, and bacteriological examination of a catheter specimen; also a record of the amount passed in 24 hours. (3) Radiography of the urinary tract. (4) Estimation of the total renal efficiency. (In some cases this might be dispensed with.) (5) The first cystoscopy—as essential as retinoscopy was to the ophthalmologist—the whole bladder was examined and the appearance of the ureteric orifices and the rate and character of the efflux from them was noted, together with a colour test. A second cystoscopy might be needed for collection of urine separately from the ureters, for location of stone or for pyelography. Such an examination involved expense and delay; it should stop when it was felt that an accurate diagnosis had been made. The necessity for complete examination of the *whole* urinary tract was, however, shown by the following case:—

A man had been under treatment for nephritis as albumin had been found in his urine. After prolonged treatment without benefit, he changed his doctor. His new adviser got the urine examined bacteriologically; coliform bacilli were found, and the patient was treated with a *Bacillus coli* vaccine. After a time, being regarded as cured, he was sent for a holiday. On the second day of his holiday he had to be admitted to hospital, where a large phosphatic calculus was removed from the bladder. On his return to Glasgow, as he appeared to be no better, he came into the Western Infirmary, where Mr. Young removed an enormous calculus, together with a functionless pyonephrotic right kidney.

Renal Infections.

Mr. A. H. JACOBS said that the symptoms of renal infections might be exhibited in a fulminating, acute, or chronic form, but all types had one sign in common—namely, the urine contained organisms and pus, the latter varying in quantity from a few cells to a thick deposit. Frequent and sometimes painful micturition, occasionally accompanied by a dull ache or pain in the loin, were the usual urological symptoms of which the patient complained. Generally the pyuria was chronic and rational treatment could only be adopted after trying to find out: (1) its source; (2) whether one kidney or both were involved; (3) to what extent the renal function had been impaired and the substance of the kidney destroyed; and (4) whether there was any complication such as ptosis, calculus, or hydronephrosis which would tend to keep up the infection or predispose to its recurrence. In about 90 per cent. of cases the causative organism was the *B. coli communis*. Many pathological conditions—particularly intestinal stasis—tended towards abnormal multiplication of these organisms, which were then readily carried to the kidneys by the blood. In the less common staphylococcal and streptococcal infections evidence of old or recent septic foci might be found on cutaneous or mucous surfaces. On cystoscopy evidence of cystitis was almost invariably found, and this explained the predominance of bladder symptoms in renal infections. Cystitis was rarely a primary disease. In the words of Boyd, "The bladder resembles the stomach, in that it makes its voice heard above that of its neighbours, although it is they that are really suffering." Having found a cystitis, it was necessary to seek further for a focus in the urinary tract, and Mr. Jacobs briefly described some of the appearances that might be found o further examination. He concluded by saying tha he had never seen any serious sequelæ from pyelo graphy, though renal colic was sometimes so severe as to require morphia. He had never carried ou this examination in the fulminating or acute types infections, and did not advise that it should be don except in certain special circumstances.

Tuberculous Disease.

Mr. J. MILL RENTON made the following gener statements:—

1. Although tuberculous disease of the kidney is alwa secondary to some other focus of tubercle, the prima disease is often difficult or impossible to detect.

2. The disease is almost always unilateral to begin wi and tends to remain so for a long period, but shows practical no tendency to spontaneous cure.

3. Its symptoms, in the great majority of cases, a entirely referred to the bladder and consist of frequent an painful micturition associated with pyuria; these may the only symptoms even up to an advanced stage of t disease. In his own experience it has been quite exception to find any pain or tenderness in the renal regions.

Any young adult suffering from pain and frequenc with pyuria might have tuberculous disease of th kidney. Rarely an attack of hæmaturia might h one of the first symptoms. Ordinary clinical examin tion was often negative, but occasionally a deposit tubercle might be found in the epididymis associate with a renal lesion, and in some cases a thickene ureter could be felt per vaginam or per rectum Bacteriological examination of the urine was of th greatest importance. Pus was present whenev there was a lesion of the kidney, but there might h tubercle bacilli in the urine without pus in cases generalised tuberculosis without a definite lesion the kidney. It was now possible to find the tuberc bacillus in the great majority of cases, and where could not be detected animal inoculation migh give a positive result. A marked *B. coli* infectio might mask a tuberculous lesion, especially in wome Cystoscopy was essential for accurate diagnos and often catheterisation of the ureters was require In a few advanced cases the latter might be impossibl It could sometimes be done later, after treatment wit tuberculin, rest, and urinary antiseptics. Shou these fail, said Mr. Renton, the following metho might be tried to show where the lesion was:—

1. Injection of indigo-carmine, either into a muscle into a vein. If the renal disease is advanced the excreti of the blue colour is usually delayed or absent on the affect side. Unfortunately, in early cases the dye is excret just as well by the tuberculous kidney as by the normal or

2. Radiograms may show a shadow where there a caseous masses or calcareous deposits in the kidney.

3. Catheterisation of the ureters after opening the bladd has been suggested, but may be very difficult or ev impossible and should not be attempted.

4. The operative exposure of both kidneys has be employed, but is not to be recommended.

5. Both ureters may be exposed extraperitoneally abo the pelvic brim (Fullerton). The ureter on one side ma be thickened, whilst the other is normal. A catheter ma be inserted through a small incision into one or bo ureters and urine collected, the small opening being afte wards closed.

This last method Mr. Renton considered sati factory in the few cases in which it was impossib to make a reasonably certain diagnosis by less drast methods. He thought pyelography quite unnecessar in the diagnosis of renal tubercle. The addition information it gave did not justify its regular use.

Renal Calculus.

Mr. J. SCOULER BUCHANAN pointed out tha colic and hæmaturia (in macroscopic or microscop amounts) were common to many renal condition When the patients were examined with X rays positive finding might not be obtained, perhap owing to obesity or because the stone did not ca a shadow. Often calcareous glands or phlebolith occupied the renal and ureteric regions and obscure or simulated stone. By cystoscopy, ureteral cathete

isation and pyelography, many cases could be cleared up. Localisation was important because it often saved the kidney from unnecessary trauma. When the kidney was laid open widely in search for stone the patients lost much blood both during and after operation, and urinary fistula sometimes followed. Hydronephrosis, if present, could be demonstrated definitely, even in the early stages, by ureteral catheterisation and pyelography. Moderate degrees of dilatation of the pelvis and calices could not be made out at operation, and the surgeon might thus return the kidney to its bed with a false sense of security as to its future. A pyelogram would give him a pictorial idea of its condition. Stones which the X rays did not show could generally be demonstrated by pyelography.

Mr. Buchanan did not regard the occurrence of colicky pain during injection of sodium iodide into the ureter as of much value from a diagnostic point of view. Once pain was complained of, the injection should be stopped. He ended by saying that he had found the newer methods of great value, and had not known any untoward condition to result from their use.

Tumours and Congenital Abnormalities.

Mr. W. W. GALBRAITH said that the vast majority of renal tumours were malignant and when renal swelling could be palpated the prognosis was grave. On the other hand, many renal tumours gave early indication of their presence by eroding a vessel and causing hæmaturia, generally painless, although sometimes accompanied by colic caused by the blood clotting. Pain in the back was often absent and was often no more than a slight ache. Early investigation of the urinary tract was essential, preferably while blood was still present in the urine. Rest in bed for a day or two would generally cure the bleeding, but its recurrence was almost certain, though it might not take place for many months, when treatment might be too late to cure. In these cases urinary investigation at the very least implied cystoscopy, and the estimation of the relative efficiency of the two kidneys. For this purpose Mr. Galbraith used an intravenous injection of 5 c.cm. of a 4 per cent. solution of indigo-carmine. Though this test was of great value in differentiating the diseased from the normal kidney, it only applied, he thought, where more than one-third of the kidney was destroyed. Thus, in the very early stages of tumour formation, cystoscopy and indigo-carmine would not help towards showing the exact nature of the disease. In such a case—and indeed in every case of actual or suspected renal tumour—he invariably made bilateral pyelograms. In the early stages all that might be seen was some elongation and thinning of the calices. It was almost essential that double pyelography be done as it was only thus that kidneys "normally abnormal" could be excluded. Variations in the normal pelvis were common. Specimens taken from either kidney when the ureters were catheterised before pyelography were of little value, for he had never found tumour cells on microscopic examination of the urine thus obtained, and any blood present might be due to trauma. In cases of hæmaturia to which no cause could be ascribed the patient should be carefully watched and repeatedly examined at intervals of a few months over a prolonged period.

In the congenital anomalies, continued Mr. Galbraith, the indications might be various, and the difficulty was to know when the tests should be applied, but where a patient complained of a swelling, or a vague pain, or indefinite urinary symptoms, and where the swelling or pain lay somewhere in the region of the urinary tract, and where no definite organ could be shown to be the cause, a full examination of the urinary tract might prove invaluable. It was without risk, and practically painless, required no more preparation than that necessary for an X ray photograph, no general anæsthesia, and no abstention from the patient's usual daily routine.

Limitations, Difficulties, and Dangers of Diagnostic Methods.

Mr. J. R. LEARMONTH, drawing attention to the need for strict asepsis, said that in uninfected cases freedom from chills and fever after the examination might be taken as showing the attainment of surgical cleanliness; it was almost certain that they were the result of temporary bacteriæmia, and during the comparable chills which accompanied pyelonephritis blood culture was positive in two-thirds of the cases. In a recent series of 500 pyelographies only seven patients had developed pyrexia above 100° F. Contra-indications to the use of the cystoscope were: (1) when the patient was aged and infirm; (2) when he was greatly weakened; (3) when there was bilateral renal impairment of an extreme degree, as detected by clinical data, studies of the blood chemistry, and renal efficiency tests; and (4) when it was apparent that no surgical procedure could be of any benefit. Under the first three conditions suppression of urine might occur after the examination. In introducing the cystoscope, phimosis, an unusually narrow meatus, or a urethral stricture might require correction. If the last-named must be dilated before the cystoscope can be passed, it was probably better to defer cystoscopy for a few days. Where mere inspection of the bladder could solve the problem, the routine passage of ureteral catheters was to be condemned. The conditions making it justifiable to catheterise the ureters were the presence of pus or blood in the urine—not accounted for by the condition of the bladder and urethra—and the need to determine the individual function of each kidney, to make a pyelogram or to identify a ureteral stone. Infection might be conveyed to a non-infected kidney by passing a ureteral catheter through an infected or tuberculous bladder, and precautions must be taken against this. Previous exhibition of urinary antiseptics helped to reduce the amount of infection; the bladder must be well washed out before the cystoscope was introduced; and in certain types of instrument the ureteral catheter might be passed while continuous irrigation went on through the cystoscope. With these precautions the risk of infecting the kidney was very slight. There might be anatomical difficulty in finding the ureteric orifices and introducing the catheters. Thus the ureters might enter the bladder at abnormal positions; the presence of a cystocele might distort the vesical picture; and in infected bladders, especially when the infection was tuberculous, scarring from cystitis and ureteritis may impede the passage of the catheter or even prevent the identification of ureteric orifice. In this case it might be necessary to expose one or both ureters in the loin. Pyelography should not be attempted (1) when a diagnosis could be reached without it—e.g., in hydronephrosis by obtaining a large amount of residual urine from the kidney pelvis; (2) in the aged, infirm, or emaciated; and (3) in acute infection of the kidney. Though it was usually taught that pyelograms should not be made on both sides at the same time, he had no hesitation in doing so when it seemed desirable, and had observed no ill-effects. The solution employed for pyelography was not in itself dangerous. It was non-irritating, non-toxic, easily sterilised, almost neutral in reaction, and flowed into and out of the pelvis as easily as water. Its only disadvantage was that it is not germicidal; germicidal media had been described, but had not come into general use. Care must be taken not to introduce too much solution. Though the patient was conscious and thus able to complain of the pain to which over-distension gives rise, the catheter might be pushed so far that its eye rested in a calyx, so that pain might be felt after the introduction of enough fluid to distend the calyx alone. This error was easily recognised and rectified by withdrawing the catheter an inch or so. The calibre of the catheter should be such that any excess of fluid could escape down the ureter. Fluid introduced at too high a pressure was apt to find its way into the intrarenal venous system, and this possibility

ruled out pyelography in acute renal infections. After the radiogram was taken the fluid should be removed from the renal pelvis with a syringe before the catheter was withdrawn. Lastly, the interpretation of the pyelogram was often beset with difficulties, and they must always be considered in the light of the clinical data.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

Ultra-Violet Light Therapy in a General Hospital.

AT a meeting of the Federation held on Nov. 27th Dr. JUSTINA WILSON, after paying tribute to Bernhard, Rollier, and Finsen as founders of modern light therapy, claimed that a rational therapy could only be based on knowledge of the physiological and pathological relations of the human organism to light. Ultra-violet light was no indifferent or harmless agent. French authors had recently described profound auto-intoxication as the result of irradiation, and Guillaume and l'Agrifoule had shown that while a strong source of ultra-violet light might increase the resistance of some organs, it undoubtedly decreased the resistance of the hæmopoietic organs. In many cases ultra-violet light acted like protein shock, bringing about a prolonged negative phase. At the present time empiricism had outrun scientific research, and it was necessary to work at this problem, for indiscriminate handling meant failure. The first thing was to realise the inferiority of all sources of light to that of the sun. The second was to understand the quality and quantity of radiation given by the chief types of lamps. Artificial sources of light could be roughly divided into three classes :—

1. Those with chiefly visible rays and some (infra-red) invisible—e.g., all heating apparatus from the match to the electric arc, and all apparatus for radiant heat, hot bottles, &c.
2. Those whose emission produces a single type of (ultra-violet) radiation—i.e., the different forms of mercury vapour and Kromayer lamp.
3. Combined sources such as carbon arcs, arcs with metal (iron, tungsten) electrodes, and carbon arcs with metallic cores.

Ultra-violet therapy was indicated for surgical tuberculosis and rickets. General light baths in tuberculosis of joints, bones, glands, and skin. Tuberculous peritonitis, both serous and dry, reacted well to ultra-violet light, the only exception being when the disease arose from a tuberculous focus in the female adnexa. In fact, all forms of urogenital tuberculosis were refractory to light. Apart from tuberculosis, rickets, wounds, ulcers, burns, ununited fractures, no disease was an absolute indication for light; but it was useful in convalescence, after surgical operations with loss of blood, after infective conditions such as typhoid, and as a prophylactic after illnesses which might lead to tuberculosis, such as influenza, measles, and pleurisy. The effect of light on sleep, appetite, and blood regeneration was marked. Its value in whooping-cough was not yet settled; Huldschinsky had had good results in some 30 cases. The good effects observed in arthritis, fibrositis, neuritis, or sciatica were often due to heat. When the toxic focus underlying these conditions had been removed light was a valuable adjunct because of its physiological invigorating effect.

A rational light therapy was based on the great law of light, which runs: To have effects, light must be absorbed. The basal cells of the epidermis were endowed with specific light sensitivity; light acted directly on these cells, either stimulating and vitalising their functions and secretions, or destroying them. Light also had an indirect effect on the deeper tissues and organs. It was difficult to understand how short non-penetrating rays could affect the body generally, yet a whole series of phenomena proved their powerful effect on protein, carbohydrate, fat, and mineral metabolism; also on the blood picture and on muscle and nerve. The chief theories put forward to explain this were Schläffer's energy theory, and Rollier's theory of transformation. The simplest and most rational explanation was due to Jesionek, who believed that absorbed light stimulated certain vital cell products which reached the tuberculous focus via the blood and lymph stream.

Three phenomena expressed the effect of light on the human skin: (1) hyperæmia, (2) erythema, (3) pigmentation. The first was an immediate effect primarily due to heat rays dilating the capillaries and lymphatics, and giving rise to increased elimination of toxic products and increased phagocytosis. Erythema was a late response of the skin to the chemical rays. Direct light therapy might be used to stimulate the normal functions of the basal cells—e.g., the germinative function in the treatment of non-healing wounds, skin grafts, indolent ulcers, burns, and non-uniting fractures. Light could also be used to stimulate and regulate the keratin-forming power of the basal cells, in any condition where this was abnormal, such as eczema, psoriasis, acne, or alopecia. In acute eczema good results could be achieved by using the cold light of the mercury vapour lamp, and avoiding flooding the capillaries by infra-red rays. Strong doses were necessary, and the use of a sensitiser (such as salt and water) was an advantage. In psoriasis plaques should be first removed by using white precipitate ointment overnight, 10 per cent. salicylic ointment in the morning followed by a soap bath, then a general light bath, and finally intense and direct treatment to the worst parts. In acne vulgaris, where there was always disturbance of the keratotic function of the cells, a combined source of light was often better than the mercury-vapour and the Kromayer lamp when much induration was present. The greatest triumph of ultra-violet light was in the treatment of lupus by photo-chemical inflammation. Jesionek's technique aimed at the production of periods of acute inflammation by mercury vapour, alternating with colloboric compresses, general light baths being given in addition.

In gynæcology, light was an indispensable adjunct to conservative treatment of subacute and chronic inflammatory conditions of adnexa, vulva, and vagina. In amenorrhœa arising from infantile conditions good results were gained by a system of cross-fire radiation to the ovary from within and without. Contraindications were acute inflammatory conditions and the menstrual period, as in both of these the bactericidal power of the blood was reduced.

ROYAL PHYSICAL SOCIETY OF EDINBURGH

AT a meeting of this Society on Nov. 21st Dr. DOUGLAS GUTHRIE read a paper on

Pharyngeal and Laryngeal Pouches in Man and Animals.

He said that pockets, or *ganahs* as they are called, were sometimes artificially produced by criminals in India by means of a lead weight attached to a string. The leaden disc was retained in position continuously and served to deepen the normal hollow (sinus pyriformis) at the entrance of the larynx, and the pouch which was thus gradually formed became a safe hiding place for coins or precious stones. The pouch differed in site and origin from the pharyngeal diverticulum which occasionally developed behind the larynx. This was of the nature of a hernia and sometimes demanded surgical attention. It was interesting to note that in the pig a pouch was normally present at this point in the posterior pharyngeal wall, but no such structure existed in other domestic animals. Other pouches such as were found within the larynx were of interest to the comparative anatomist. In man, there was a depression, the laryngeal ventricle, just above each vocal cord, and from this a little pouch or saccule extended upwards for a variable distance. In the gorilla and chimpanzee this extension, uniting with its neighbour

of the opposite side, reached as far as the root of the neck; in other monkeys the two united saccules occupied a large cavity in the hyoid bone. Absent in the sheep and ox, the ventricle and saccule were found in the dog and pig, whilst in the horse the saccular part was relatively large. Advantage was taken of this fact in the operation of ventricle-stripping to cure "roaring" in horses. Dr. Guthrie demonstrated the shape and contour of the saccule in various species by means of a series of casts. The function of laryngeal pouches was, he said, uncertain. They might serve to lubricate the vocal cords or might act as resonating chambers, or they might simply be the degenerate remains of the accessory air reservoirs seen in the frog and in birds.

THE PROBLEM OF GOITRE.

INTERNATIONAL CONFERENCE HELD IN BERNE, AUGUST 24TH–27TH, 1927.

Report by Dr. F. DE QUERVAIN,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF BERNE; HON. FELLOW OF THE ROYAL SOCIETY OF MEDICINE.

THE first suggestion of an international conference on goitre came from Prof. Aschoff (Freiburg) who proposed a meeting of scientific workers to study the behaviour of goitre throughout the watershed of the Rhine. The idea was handed on to the Swiss Goitre Commission by the late Prof. Hotz (Basle), but the Commission determined to widen the inquiry to include all countries and continents, and to limit the first conference to the purely scientific problems of pathological anatomy and physiology, and endemiology and ætiology, leaving clinical questions for discussion later. At a later stage was added a section of prophylaxis, to form, as it were, a transition to the practical questions. Preparations were made to hold the conference in 1923, but the political situation of Europe made postponement desirable, the delay having the advantage of bringing in all countries interested in goitre. Only from the United States of America was the representation less complete than had been hoped. The decision not to throw open the conference to general discussion, but to invite a limited number of scientific workers of all shades of view to speak on important problems, justified itself in practice and may serve as a model for similar large congresses in future.

Pathological Anatomy.

In this subject international discussion was especially necessary since mutual understanding of scientific work is made increasingly difficult by differences in nomenclature. The preliminary papers of ASCHOFF, WEGELIN, and MARINE, and the remarks made in the discussion by ROUSSY, JOSSELIN DE JONGH, and others helped notably to clear the situation, with the help of an exhibition of naked-eye and microscopic preparations from most European countries. While unity prevailed over goitre of the new-born and adolescent, and over colloid goitre, the nature of nodular parenchymatous goitre gave rise to a lively discussion. Wölfler's conception of its origin from fetal remains hardly gained any support and should be regarded as finally wiped off the slate. On the other hand, no complete agreement could be reached whether goitre nodules are to be regarded as "parenchymatous overgrowths" or as "adenomata." The former interpretation was supported from the French side, the latter from the German and Swiss side. Fundamentally this is not a thyroid problem, but rather one of general pathology—namely, to determine the boundary between limited hyperplasia and new growth. It was therefore not to be expected that the question would be cleared up by taking the thyroid as an example. The determination was reached to set up an international nomenclature, using as its basis in essentials the so-called Berne scheme. A small commission of pathological anatomists was entrusted with this task.

Of special interest for the estimation of thyroid enlargement were the series of preparations set up by the pathological institutes of Freiburg (Aschoff) and Würzburg (B. Schmidt) dealing with the development of the thyroid at various periods of life, and in goitrous and non-goitrous regions. The life-curve of the thyroid, especially brought out by Aschoff, will contribute materially to a clear limitation between normal and morbid processes. If a survey is taken of material derived from various parts of Europe the conviction is soon reached that endemic goitre is fundamentally the same everywhere, and that local differences, apart from the absolute frequency of goitre, are due to relative frequency of the separate forms. In the centre of a region where goitre is endemic, the nodular parenchymatous form prevails; at the periphery colloid goitre, diffuse at first, becoming nodular in later life; in the goitrous parts of the lowland separated from the great endemic centres diffuse colloid goitre only exceptionally becoming nodular.

The most severe form of goitrous thyroid change—namely, the cretin goitre—was discussed principally by WEGELIN. The cretin's thyroid is either atrophic with little adenomatous nodules, or there lie in an atrophic matrix nodules of some size, as a rule of a parenchymatous character, in which all forms of secondary changes may occur—calcification, cyst-formation, &c. In the cretin goitre colloid is only occasionally formed. The whole cycle of goitrous development with its various sequels was set out most clearly in the paper of Marine, who unfortunately was prevented from being present himself.

The discussion on struma maligna was opened by WEGELIN, whose recent book on the pathology of the thyroid is likely to remain for some time as the standard work. The type described by Langhans as "sprouting struma" is attracting more and more the attention it deserves. The only point on which agreement was not reached is the significance of the so-called hæmangi-endothelioma of the thyroid. That this is a special kind of tumour is put beyond a doubt by the Berne material, but its actual nature remains in dispute. Whereas Wegelin, in agreement with Hedinger, regards the tumour cells as endothelial, Roussy considers them epithelial. Cysts and hæmorrhages characterise the majority of these growths.

The conference next turned to consider the anatomical and physiological studies of WILLIAMSON and PEARSE, who draw a sharp distinction between secretion tissue and colloid storage tissue. Should the results of these two investigators be confirmed they certainly mark the greatest advance of recent years in our knowledge of this subject and will be of very real value in the interpretation of the histological picture. Their microscopical preparations were, on this account, of special interest to the members of the conference.

Pathological Physiology of Endemic Goitre.

To the great regret of the conference, PLUMMER (Rochester, U.S.A.), who was to have introduced the subject, was prevented from coming himself and could not send his introductory paper in time. In his place DE QUERVAIN introduced the discussion. He began by laying emphasis on the fact that the pathological physiology of endemic goitre is not covered entirely by the problem of thyroid physiology and its disturbances. The morbid process which leads to goitre may influence the organism in other ways, first, via damage to the parental organism; and, secondly, by direct action on the body tissues, as also on the other endocrine glands. But damage to the thyroid itself occupies the foreground, and is in much greater degree accessible to anatomical, clinical, and experimental study than the other possibilities mentioned. From the practical standpoint, therefore, the physiology of endemic goitre must concern itself in the first place with the problem of the thyroid gland. After this preface de Quervain spoke of the influence of endemic

goitre on the thyroid function, showing how, in the majority of cases, the function is disturbed in a manner not as yet accessible to demonstration. In a small number of cases a secondary Basedow-effect is found, not only in diffuse, but also in nodular endemic goitre. This Basedow struma is geographically, and in part also genetically, to be distinguished from genuine Basedow,[1] even if a schematic clinical distinction is not possible. Frequently the Basedow-effect is released by a dose of iodine as small as 0·5 mg. daily. Much more often, however, the goitrous noxa leads to a diminution of thyroid function, whose clinical expression is seen in the picture of endemic cretinism. We must therefore distinguish between the cretin with atrophic thyroid and the classical symptoms of thyroid insufficiency on the one hand, and the goitrous cretin on the other hand, in whom the clinical picture, owing to later and less severe change in the gland, is a less complete one. In order to explain what are essentially plus-thyroid conditions as well as the minus-thyroid condition of the cretin, de Quervain assumes the possibility of a dysthyroid component. This may consist either in an abnormal blend of the various components of the secretion, or in the production of entirely unphysiological secretions. The former assumption is rendered very probable by present-day research. For the second assumption no absolute proof for or against has yet been brought forward. The significance of the striking dissociation in the picture of cretinism would be most easily explained by the assumption of a dysfunction. It is, however, possible that the goitrous noxa acts also on the body via the parental organism (heredity), and finally it may directly damage the tissues of the goitrous person, including the other endocrine glands, as has been taught by Virchow, Scholz, Ewald, and Bircher. Dealing with the circulation of iodine between the blood and thyroid de Quervain showed, on the basis of his own work and that of Sturm and Veil, that the iodine level in the blood possesses great constancy, and that its height depends on the functional activity of the thyroid gland. It is at its highest in Basedow, at its lowest—only about half or so of the normal height—in the cretin. If the latter is given iodine in excess it is rapidly excreted, since his thyroid gland is not in a position to synthesise it in the normal way. On the other hand, the iodine in the thyroid is partly brought into another chemical combination, whether it is stored up as colloid or whether in this new combination it leaves the thyroid at once without being stored.

The second paper was read for Prof. VON EISELSBERG by his assistant, Prof. BREITNER, who attempted on the basis of his earlier and recent work to explain the various functional conditions of the thyroid by the demands placed on it by the body. He distinguishes between hyporhœic and hyperrhœic conditions, denotes the different behaviour of the histological picture as eutrophic, hypertrophic, and hypotrophic. By combination of these possibilities he derives the various forms of goitre as they actually occur in practice. His classification is therefore, in contrast to that of Wegelin, Aschoff, Bérard, McCarrison, and Williamson, a combination of anatomical and functional. It approaches, on the other hand, the classification of Williamson in that it depends on a subjective estimation of the trophic condition of the gland. In opposition to his view the majority of those present emphasised the necessity of a purely descriptive classification for international use, independent of any theoretical conception. This does not prevent Breitner's view as well as that of Williamson from being of interest as working hypotheses. The action of iodine is construed by Breitner as corresponding to a "functional direction" of the gland—that is to say, in the hyperrhœic gland it gives rise to colloid storage, and in glands already overflowing with colloid it releases the secretion.

[1] *Basedow* is here used in the continental sense of exophthalmic goitre; the convenient compounds *Basedowizierung* and *basedowificata* have been paraphrased with difficulty.

Ætiology and Epidemiology.

Prof. LÉON BÉRARD'S (Lyon) clear and succinct introductory paper started with French experience but touched the problem in its whole extent. Bérard takes the standpoint of multiplicity of ætiological factors and hazards the suggestion that the totality of the factors causing goitre disturbs iodine metabolism in the body—that is to say, produces iodine deficiency. Drinking-water plays the chief rôle as carrier of the yet unknown noxa. Age, sex, and heredity play a secondary but not unimportant rôle. Bérard's paper was supplemented by a valuable contribution from McCARRISON which in his regretted absence was summarised by Sir JAMES BERRY. In the same way as the latter laid emphasis a quarter of a century ago so McCarrison still insists that goitre is a syndrome which includes a great number of conditions of various origin. The proof of this he gave in a paper summarising his important and fruitful life-work. For endemic goitre in the narrow sense—goitre of the Alps and the Himalaya, as McCarrison puts it—he finds the pathogenetic explanation in a reasoned combination of iodine deficiency theory and infection theory. The latter is warmly supported by Galli-Valerio, who is only an adherent of the iodine deficiency theory to the extent that iodine is able to neutralise the noxa causing goitre where the latter is not acting too intensively. Iodine is the antidote whose employment should not prevent an interest being taken in all the essentials of general hygiene.

E. BIRCHER makes distinction between the endemic goitre of the Alps and mountainous regions of Asia and the goitre of the European and American plain. On the other hand, he finds it necessary to bring in cretinism, cretinoid deafness, and endemic goitrous heart into the conception of the endemic goitre epidemic. In order to judge of the effect of prophylactic measures the variable character of the endemic and the shifting of its maxima must be borne in mind.

Discussion of the ætiology of goitre gave the impression of fairly general agreement on the assumption of a toxic cause which in a way still unknown is rendered more or less harmless by the physiologic intake of iodine with the food. Goitre arises in general where either iodine deficiency exists or where the noxa works too intensively to be neutralised by the quantity of iodine normally present in the body.

On the question whether water or other food is the chief vehicle of the goitrous noxa, and on the method of action of iodine, various views are taken within the limit of this theory. Almost unanimous was the refusal of a specific goitrous infection. As this point two views were brought forward which cannot remain unmentioned, although they met with not a little scepticism. CROTTI (Columbus, Ohio) found in the blood of goitre-bearers spirilla and protozoa of various kinds, a whole flora or fauna which he thinks he can show also in the water of goitrous neighbourhoods. Dr. FOLLEY (Paris) related similar independent findings and demonstrated them after the conference in a case placed at his disposal in the surgical clinic. These findings must be tested, for in medicine the unlikeliest sometimes turns out to be true.

Prophylaxis.

The three introductory papers by WAGNER JAUREGG (Vienna), MUGGIA (Sondrio), and SILBERSCHMIDT (Zürich) all recommended on the ground of existing experience general prophylaxis by means of iodised salt in physiological dose (5 mg. KI to 1 kg. salt). The carrying out of this prophylaxis in Austria during three and a half years has been accompanied by a perceptible retrogression in school goitre and the drawbacks of the proceeding (iodine-Basedow) are, according to Swiss statistics, not of a kind to prohibit its employment. The severest symptoms attributed to iodised salt come from North America where an altogether unphysiological dose—namely, 0·2 g. KI per kg. salt, has been added; that is to say, a dose which at the time of the first experiments of the kind in France 70 years ago had already led to iodism

Basedow. Moreover, the addition should in the general opinion be optional; the possibility should be offered of obtaining also iodine-free salt. For certain neighbourhoods Muggia regards the so-called "dumb" iodine prophylaxis to be indicated. Certainly it is argued by individual authors that any iodine prophylaxis must be carried out individually, but if this were done the chief aim of prophylaxis—its general influence of childhood in the fœtal period—would be lost. Only an influence exerted on the whole population exposed to goitre can lead to a result. Further, the argument that there are goitres in which iodine gives no result cannot be seriously maintained, for they are either the end-results of the usual endemic goitre (cysts and other degenerative forms), whose occurrence could have been prevented by timely iodine prophylaxis, or they are forms of goitre, like those described as lymphadenoid goitre by Williamson, Pearse, and McCarrison, which play practically no rôle in the goitrous areas of the Alps. For where these latter occur or predominate the observations made by McCarrison in regard to the kind of food-supply would have to be considered.

Alongside the general influencing of the goitrous endemic by physiological iodine SILBERSCHMIDT specially emphasises the value of an individual treatment of school goitre with iodine by means of small doses (1 to 3 mg.), such as has been carried out specially in Switzerland, but also in Austria, and to which, given medical supervision, no drawback has been observed. The results of this school prophylaxis, or more correctly school treatment, were illustrated by wall diagrams from various countries.

The fear that physiological iodine addition to salt or cattle might cause a reduction in the production of milk or in the reproductive power has been set aside by experiments carried out by Dr. Stiner at the instance of the Swiss Health Office. In these the influence of iodine salt was found to be favourable in both directions. Interesting in this connexion are the observations of Nicolaysen and Lunde (Norway), according to which the feeding of fish with an iodine-containing fodder hinders the formation of goitre.

Towards the prevention of iodine-Basedow much would be gained if the administration of iodine preparations to patients, apart from doctors' prescriptions, could be entirely forbidden.

The aims of goitre prophylaxis, as brought out in the discussion, may be shortly summarised as follows. For man and cattle to supply the necessary physiological ration of iodine. For the already marked school goitre to combat this by individual iodine treatment in medical hands. To ensure a normal composition of food-supply containing vitamins. Finally, to combat the misuse of iodine in unphysiological doses, specially in the adult. Should a more general application of these principles result, the conference will have done something not only for the scientific recognition of endemic goitre, but also for its abolition.

A Retrospect.

This concluding sentence recalls a historical incident. One of the first, if not the first, scientific and partly international conference on endemic goitre and its causes took place in Lyons in the year 1841. Discussion turned there as at present on the influence of drinking-water, height above sea-level, climate, and biological conditions. It was then, as now, set out that, for example, in Valais, Switzerland, the number of goitrous persons had diminished since sanitary orders had been enacted. At the conclusion a letter was read from Dr. Prévost (Geneva) which ascribed goitre to the absence of bromine or iodine in drinking-water. This idea of Prévost was followed up ten years later in Paris by the chemist Chatin, whose observations were confirmed in essential points by Dr. von Fellenberg, chemist of the Swiss Health Office, and by MacClendon. The whole prophylaxis discussion of this year's goitre conference has its roots in the short communication of Prévost to the conference of 1841.

Any members of the conference who desired at its conclusion to have practical demonstration of goitre and cretinism were bidden by DE QUERVAIN to the surgical clinic and to one of the institutions of the Canton of Berne in which more than 100 cretins are cared for and put to useful work corresponding to their abilities. By the side of cases of pure athyreosis, having no connexion with cretinism, he demonstrated on the film and in person cretins of all types with and without goitre, and the visitor could form his own picture of the damage to which the goitrous endemic leads in its worst grades and draw his own conclusion as to the necessity for a general campaign.

He could also convince himself of the validity of the remark made by Maffey and Rösch in 1844: "that the belief in a 'normal' cretin or in a cretin prototype can only hinder the approach to truth and that only abundant experience and long-continued observation will allow us to recognise the pathognomonic signs and to distinguish them from accidental symptoms."

Reviews and Notices of Books.

THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY IN THE WORLD WAR.

Vol. VI., Sanitation. Washington: Government Printing Office. 1926. Pp. 1141. $3.25.

Vol. XI., Surgery. Part I. 1927. Pp. 1324. $4.

THESE two books form part of a series issued by the War Department of the U.S. Federal Government. Vol. VI. is devoted to sanitation, and its detail is overwhelming; for example, 44 pages are devoted to an account of how the army hut developed, and how the space allotted to each man increased from 27 square and 291 cubic feet to 53 square and 528 cubic feet, with 5 feet between the men's heads as they slept. There is need, in fact, of an index-handbook to announce briefly what the sanitarians decided, giving references to the volume and page where their preliminary investigations are recorded.

The cause of hygiene in the American army during the war was helped by the prestige that had been gained in peace-time, at Panama and elsewhere, by Surgeon-General W. C. Gorgas. With three other physicians, he was early put on a housing board, most of whose recommendations were at once accepted; one of them, however, seems to have been completely overlooked—namely, "that the outer walls [of the huts] be so constructed that sections may be raised, so as practically to convert the dormitories into outdoor sleeping porches." How useful this provision would have been found in the influenza pandemic may be guessed from the fact that at East Boston, Massachusetts, the open-air treatment of influenzal pneumonia reduced mortality by 50–70 per cent.[1] Amongst American troops the influenza epidemic was first noted on Sept. 7th, 1918, in three transports (from whence unstated) five days before reaching Archangel. On the following day it broke out at Camp Devens, Massachusetts, planned for 30,000 men, but now overcrowded with 45,000; here 10,000 cases were reported within three weeks. The peaks of the epidemics occurred among the United States troops in France in the third week of September, in the transports going to France about Oct. 11th, in the French army in the third week of October, and in the British Expeditionary Force in the first week of November.

There are many fascinating essays in this volume, on subjects including baking as influenced by the pH of the water, the addition of serum to the dough, the choice of camp sites, and antimalarial work, whose cost varied between £20 and £700 per square mile. "Shoes" (anglice, boots) were very carefully chosen for the army before the war, but were found too light

[1] Ministry of Health's Report on the Pandemic of Influenza, 1920, p. 265.

for the trenches; the British pattern lasted six months instead of four, and "several millions" were therefore ordered, but, being made on European lasts, did not fit United States soldiers, and are said to have given the 42nd Division sore feet on their march into Germany. There are very valuable notes on feeding troops in transports, and on the importance of the "food and nutrition" officer, who does nothing else but examine the messing of units, trying to improve it.

Much trouble was taken to lessen or prevent venereal disease in France. There were lectures and other diversions, and the High Command did its best to prevent infectious contacts and, alternatively, to secure prompt prophylactic treatment. Congress had early ordered the suppression of prostitution in the neighbourhood of camps in the U.S.A., but in France all that could be done was to put brothels out of bounds. The French became alarmed; they had hoped that venereal disease would have been confined to the brothels, and were now anxious lest it should become generally disseminated. They alleged that rape increased; this proved to be an error. Clandestine prostitutes, when found, were banished from about United States camps, and to associate with them in Paris was a military offence. Prophylactic treatment had been adopted by the United States army in 1912. It was ordered on July 2nd, 1917, that every man exposing himself to the risk of venereal disease should take prophylactic measures; if he did not do so, and became diseased, he was to be court-martialled for incapacitating himself by neglect. Further, it was ordered on Dec. 18th of the same year that every man returning from leave must, if sober, sign a certificate that he had not risked contracting venereal disease, or else must adopt prophylaxis, which would be administered to him if he was drunk. This order also declared that a high venereal rate in a unit was evidence that its discipline was bad, and was therefore a slur on its commander, casting doubt on his fitness for promotion. It also limited leave passes to four hours, not later than 9.30 P.M. Prophylaxis had fewer failures after four hours' leave than when all-night passes were issued. Much depended on how prophylaxis was done. Each station was in charge of an orderly who was supposed to administer the treatment. But when inquiry was made into 142 failures in one division it appeared that 102 of the men had done the disinfection themselves, that 60 had been given no soap, and 10 no ointment. When prophylaxis was supervised for six months by a zealous medical officer in a large camp of some 2000 men it was found that the only men infected were those who had neglected precautions. After the Armistice men were given a week's leave at Government expense at Aix, Biarritz, or other selected centres. They were inspected before they left their units, a doctor and orderlies with prophylactic equipment travelled with them on the leave-train, and they were again inspected on arrival, being warned of the risks of that place, and told what areas were out of bounds and the positions of the prophylactic stations, which were multiplied if necessary. In the first half of 1919, 415,755 men went thus on leave, 50 per cent. took preventive measures, and 323 cases of venereal disease occurred (0·25 per cent. of those who risked infection, and 0·08 per cent. of the whole). The success in the army generally was much less, for between September, 1918, and June, 1919, the number of cases was equivalent to an annual rate of 4 per cent.—i.e., no lower than that of the British army. The Commander-in-Chief was dissatisfied, made a personal inspection, and noted that brothels were not everywhere put out of bounds, and that prophylactic stations were not always easily accessible or well kept. All this goes to show how difficult it is to prevent these diseases, even when the aim is energetically pursued.

Vol. XI. is devoted to surgery. Its first part, here reviewed, treats of general surgery, orthopædic surgery, and neurosurgery, and is apparently produced regardless of expense, being fully illustrated, partly in colour. In the section on general surgery all the means employed by the combatants on the Western front for the purpose of destroying or disabling one another are first described—sometimes, we think, unnecessarily. For instance, a picture of a United States 14-inch coast defence railway gun has little bearing on the study of wounds in the world war, even though it was "evolved entirely by the United States Ordnance Department." Profusion of illustrations is, however, a fault on the right side, though it may swell the size and increase the weight of the book. Statistics, anæsthesia, wound shock, and localisation and extraction of foreign bodies under X ray control are discussed at length, and there are chapters on gas gangrene, tetanus, and trench foot. Wounds are classified and discussed in chapters devoted to various regions by divers authors. The chapter on the end-results of fractures of long bones seems to us to belong more properly to the orthopædic section, which occupies 200 pages of this volume.

The successful organisation of the division of orthopædic surgery was largely due to the foresight of the members of the American Orthopædic Association, at the annual meeting in Washington in May 1916, when a resolution was passed that there should be appointed a preparedness committee "to consider the needs and equipment of orthopædic hospitals should such be required." In July, 1917, the suggestions made by the association were accepted by the Surgeon-General. The work of the division was divided into two parts—namely, the preparation of recruits from an orthopædic standpoint, and the prevention and treatment of deformities and disabilities caused by enemy action. The first part dealt with flat-foot and other static disabilities, such as faulty posture which seem to have caused far more trouble among recruits and trained men than was observed in the British army. A number of American orthopædic surgeons were lent in the spring of 1917, at the request of Sir Robert Jones, to help in the military orthopædic hospitals in Great Britain. These officers rendered invaluable help, and at the same time acquired a knowledge of the special circumstances and ways of dealing with them, which was afterwards very useful to the American Expeditionary Forces. Another smaller group of American orthopædic surgeons went overseas with the first American base hospital unit which had been organised in the United States. Profiting largely by British experience splints were standardised, and ultimately the number of types was reduced to ten. A manual of splints and appliances was issued and revised when necessary. Various forms of the Thomas splint and the Balkan frame were largely used with good results. These are all well represented in the illustrations to this section. In the treatment in France a method of "radial control" was established whereby the fracture of a joint case remained under special care all the way from the casualty clearing station to the hospital ship which carried the patient back to the United States. Until such a method was established it was found that many fractured limbs reached home with badly fitting splints and malunited bones.

In December, 1917, a special training battalion camp was established in France for the training of men physically unfit for marching and combatant duty—men in whom physical defects had developed or had been accentuated since entering the army. There were malingerers among them, but in the opinion of the anonymous writer of the chapter a large number were men of insufficient muscular development. The account of this work of restoration is of great interest, but it is too large a subject to be successfully epitomised here. A large number of the men were not returned to the firing line, but rendered fit enough to do work as hospital orderlies, motor drivers, and the like. Great attention was paid in the orthopædic division to the care of the soldiers' feet and to the modification, when necessary, of his boots. Recruits with insufficient muscular

strength apparently constituted, everything considered, the most troublesome group.

Two chapters are devoted to fractures of the upper and lower extremities, and illustrated by many clear X ray prints. The treatment adopted did not differ essentially from that used in British hospitals, but the Americans seem to have used the Hodgen splint more freely. Chapter V. gives a most interesting and valuable account of the treatment of non-union in atrophic long bones and in chronic suppurative osteitis by autogenous bone-grafts. Most of these were taken from the healthy tibia with the Albee saw. The crest of this bone was first used, but afterwards its inner surface was preferred, because regeneration of bone was better there. The inlay type of graft was used in the tibia, and usually on the forearm. For the humerus and femur the intramedullary, or as it is here called, the intermedullary, graft was found to answer best, owing to the lack of substance to hold an inlay. In some cases one end of the graft was intramedullary, and the other inlaid on to the condyles and supracondylar region. A study of this chapter with its case-reports and X ray pictures and detailed accounts of procedure will well repay any surgeon who is about to undertake an operation for non-union of a fracture. The two chapters on the amputation service and care of the amputated in the United States are full and well illustrated. American experience and practice seems to agree with our own, but much more elaborate types of provisional artificial limbs were supplied in the United States than in Great Britain. Nearly all the types of legs shown in these illustrations had artificial feet instead of the peg or block usual in our temporary prostheses. The supply of permanent prostheses seems not to come within the province of the medical department.

The section on neurosurgery begins with a chapter on organisation. The number of available surgeons with special experience of head injuries was small, and it became necessary to instruct a number of officers for duty in this subservice. In addition to such instruction, the senior consultant in neurological surgery, American Expeditionary Force, issued full directions to neurosurgical teams, which are here reprinted and which were of the highest value. The advisability of early treatment is shown by the facts here quoted, from which it appears that in the autumn of 1917, in a series of 200 cases operated upon in a British casualty clearing station which was given over entirely to wounds of the head, the mortality was 28·5 per cent., while a similar series operated upon by members of the same team in a base hospital had a mortality of about 45 per cent. The spinal cases did very badly throughout, as was anticipated. The remaining 12 chapters deal with various aspects of neurological work, including five on peripheral nerve injuries and their treatment. The results of 470 operations on such cases, whether in the nature of neurolysis or of suture, yielded 34 per cent. of "good," and 36 per cent. "mediocre" results, and 26 per cent. "failures." As is pointed out, the estimation of good and mediocre results rests on no accurate basis, and is largely influenced by the personality of the observer. The writer of this article says of nerve transplantations: "The employment of the transplant, either 'auto' or 'homo,' as a practical method of bridging defects in peripheral nerves has proven a dismal failure in the hands of surgeons of our country." A report of a number of interesting experiments on animals, made to investigate the formation of neuromata in severed nerves, concludes with the statement that absolute alcohol injected into the nerve 2–2·5 cm. from its cut surface in several small injections arranged so as to involve all parts of the nerve trunk, is a procedure which is successful in preventing neuroma formation, thus vindicating the method of those surgeons who have adopted such a procedure as a routine in re-amputation or the treatment of painful bulbous nerves in stumps. The section concludes with a full report of experimental observations on nerve-transplants.

PSYCHE MINIATURES.

By Various Authors. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1927. 2*s.* 6*d.* each.

Diagnosis and Spiritual Healing. By F. G. CROOKSHANK, M.D. Lond., F.R.C.P. Pp. 101.

Rheumatic Diseases. By MATTHEW BURROW RAY, D.S.O., M.D. Pp. 91.

Dermatological Neuroses. By W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P. Pp. 99.

Idiosyncrasies. By Sir HUMPHRY ROLLESTON, Bart., K.C.B., F.R.C.P. Pp. 119.

On History. By A. L. ROWSE, Fellow of All Souls College, Oxford. Pp. 103.

Emergent Evolution. By WILLIAM MORTON WHEELER, Ph.D., Professor of Entomology at Harvard University. Pp. 57.

Man a Machine. By JOSEPH NEEDHAM, Fellow of Gonville and Caius College, Cambridge. Pp. 111.

THESE little books belong to a series which is divided into two categories, medical and general. The general section covers a great deal of ground upon which modern medicine has made definite encroachments, while on reading the names of the various authors contributing to the medical section we can estimate that the instruction provided will be well informed and sound. Sir Humphry Rolleston gives an extraordinary number of examples of individual reactions which differ from those ordinarily observed, whether to outside stimuli or to drugs, and the little book is rendered additionally useful by the copiousness of its careful references. Many of these idiosyncrasies being dermatological, this volume may well be read in association with Dr. Donovan's contribution to the series. Dr. Ray's concluding words give the clue to his interesting book, which may be described fairly as notes to accompany the classification of rheumatic diseases made by the Ministry of Health in the report (No. 23, 1924) upon their incidence. "Since psychic states," he says, "acting through the endocrine system, have an important bearing on metabolism, a careful and more extended study of these reactions will greatly help us to a more thorough understanding of rheumatic diseases." This teaching accords well with that of Dr. Crookshank, who reprints here the Bradshaw lecture, given before the Royal College of Physicians of London last year, upon the theory of diagnosis (*vide* THE LANCET, Nov. 6th, p. 939, and Nov. 13th, p. 995), and a paper on the connexions between medical theory and spiritual healing read before the Hunterian Society at an earlier date.

The last three books on the list belong to the general section and in each the interweaving of medicine with general science is closely displayed, but in none more than in Mr. Needham's essay. This is a reasoned contradiction, from the point of view of exact biology, of those who do not recognise adequately the methodical importance of mechanism in science; and we can see its arguments being fully employed, either with endorsement or with reprobation, by future disputants. It can well be read in association with Mr. Rowse's study of the present tendencies of history, a reproduction of a contribution to the proceedings at Christchurch of the Essay Club, in which the difference between fatalism and historical determinism is discussed. He closes with a depressing estimate of human progress based on the surmise that "a healthy Neanderthal or Cromagnon man, who might as easily dispose of a modern athlete as any gorilla, could be held excused if he thought his bald and almost jawless successor to be in the highest degree degenerate."

A series of small volumes that point the way to large thinking.

INTERNATIONAL HYGIENE.

By C. W. HUTT, M.A., M.D., D.P.H., Medical Officer of Health, Metropolitan Borough of Holborn. London: Methuen and Co., Ltd. 1927. Pp. 261. 10*s.* 6*d.*

THE habit of "thinking internationally" is growing steadily amongst intelligent men and women, and there was scope for such a book as Dr. Hutt has written. It is obvious that for an island country the health of the mercantile marine, both its own and that of other countries, is of great importance to trade, while the fact that England is on the path of migration from the mainland of Europe to the Far West means that this country is liable to infections imported from all quarters of the globe. Dr. Hutt deals in interesting detail with these and other aspects of the problems of international hygiene. He begins with one of the fundamental problems—namely, how infectious diseases are kept out of a maritime country—and goes on to discuss land frontiers in relation to infectious diseases and the various sanitary conventions. Our dependence upon the Dominions and continental neighbours for our food-supply leads to a discussion of the international problems connected with food. The chapter on the difficult subject of drug habits opens up a new field of preventive medicine, and Dr. Hutt's summary of the working of the Dangerous Drugs Acts of 1920 and 1923 is admirably balanced. Following chapters deal with the health of the seamen, and in particular the problem of venereal disease. Writing of industrial hygiene from the international standpoint, Dr. Hutt stresses the point that any restriction in industry which makes for the health of the workers should be imposed equally on all nations; the existence of an International Labour Office and of the League of Nations Health Organisation, whose work is well set out in this book, may make this a practical ideal. Voluntary work such as that of the League of Red Cross Societies is also playing a valuable part in the international field. Interchange of public health personnel, made possible by the generosity of the Rockefeller Foundation, may prove the best means of all for pooling hygienic experience, and it was presumably Dr. Hutt's visit to Austria in such circumstances that stimulated him to write this admirable book.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY.

September.—This number is mainly devoted to hereditary and family diseases. C. H. Usher gives two pedigrees of hereditary optic atrophy. R. R. James a pedigree of a family showing hereditary glaucoma. R. C. Davenport a family history of choroidal sarcoma. Major J. N. Duggan and B. P. Nanavati have discovered a family with blue sclerotics, and the same authors a family with aniridia. The juxtaposition of these various narratives is calculated to enhance their value.

October.—N. Pines contributes a paper on arterial hypertension and retinal changes. The general practitioner is sometimes appealed to by specialists to record observations of this nature and we cannot but be grateful when the appeal, as in this case, is responded to. In over a hundred cases seen in general practice the blood pressure (systolic and diastolic) was correlated with the state of the retinal vessels as revealed by the ophthalmoscope, the urine being also examined in most cases. For this work considerable experience with the ophthalmoscope is required, and this the author possesses. His analytical table, in which the various signs of degeneration of the vessels are correlated with different degrees of hyperpiesis and with cases of diabetes, is of distinct value. The different vascular signs usually looked for are tabulated and the frequency with which they were found is noted, but the main importance is attached to the sign of translucency of the secondary arteries. (In the main arterial branches the blood column is so thick that it is itself sufficient to cause loss of translucency.) When translucency was complete the blood pressure was normal in all cases. When translucency was incomplete or absent the general blood pressure was in all cases abnormally high. This is a valuable observation, but needs checking by other observers, especially in regard to the age of the patients. In elderly patients a certain loss of translucency is the rule without the existence of any unduly high arterial tension.

November.—In the second of two short papers T. Harrison Butler reports a case of monocular diplopia which must be unique. The slit lamp showed the cause of the diplopia to be a large fluid cleft in the cortex of the lens. This formed an optical opacity dividing the lens into an upper and a lower segment. These acted independently, forming an upper and a lower image upon the retina.—Tscherning's Photometrical Glasses form the subject of a paper by W. A. Wille (Java). The object is to render possible a quantitative estimation of the power of adaptation to darkness. The apparatus consists of a series of plain dark glasses and a light-tight frame. The glasses are graduated thus: No. 1 lets through one-tenth of the light, No. 2 one-hundredth, No. 3 one-thousandth, and so on. The test is a candle flame at half a metre distance and the darkest glass through which this can be seen is the measure of the power of adaptation. It can be used as a measure of night blindness in any disease where this is a symptom. A differentiation must be made between the first or primary adaptation which takes place within 10 or 15 minutes, and the secondary which takes place within half to three-quarters of an hour.

Reports and Analytical Records

GENASPRIN.

(GENATOSAN, LTD., LOUGHBOROUGH, LEICESTERSHIRE.)

Genasprin is an acetyl salicylic acid (aspirin) preparation put up in the form of tablets convenient for the treatment of headache, toothache, neuralgia, neuritis, rheumatism, also for influenza and all feverish conditions. The tablets when analysed were found to contain:—

Acetyl salicylic acid	80 per cent.
Starch	20 „
Ash	Trace.

Free salicylic acid was absent.

The weight of each tablet is 6·5 gr., equivalent to 5 gr. of pure acetyl salicylic acid.

"MINTIES."

(JAMES STEDMAN-HENDERSON SWEETS, LTD., SWEETACRES, SYDNEY, AUSTRALIA.)

Minties are a hard opaque white sweet with a pleasant but not too pronounced flavour of peppermint. They dissolve slowly in the mouth, maintaining the throat in a moist state, and do not adhere to the palate. Analysis shows that the sweets have been made from pure and wholesome materials. Each sweet is wrapped in waxed tissue paper which keeps it in a dry condition and free from extraneous contaminations.

Messrs. ALLEN & HANBURYS, Ltd., have prepared and are now in a position to supply, liver in the form of a fine powder, which is palatable and readily taken by the most fastidious patient. Two ounces of this product are equal in activity to eight ounces of fresh liver. The powder is supplied in 1 oz., 2 oz., 4 oz., and 8 oz. bottles.

THE LANCET.

LONDON: SATURDAY, DECEMBER 10, 1927.

THE SUBNORMAL SCHOOL CHILD.

Principiis obsta: withstand the beginnings; the remedy is prepared too late when, through long delays, diseases have become rooted. OVID'S maxim is illustrated nowhere so well as in the experience of the school medical service. For it is increasingly clear that the school doctor does not see the beginning of many constitutional diseases even in the 5-year-olds as they first enter on school life. Sir GEORGE NEWMAN in his annual report [1] tells us that from one-quarter to one-third of school entrants need medical attention; and with the majority of this group it is not merely a defect here and there that requires to be put right, but is too often a degenerative process, a delicacy of the whole system. And we now seem to have approached the position where this yearly recurring burden of disease shows no substantial change for the better. The variety and vagueness of the terms used to indicate the child in poor physical condition—malnourished, delicate, debilitated, subnormal, neuropathic, and so on—show the difficulty found in defining the picture, and, owing to wide personal variation, even among trained observers, in judging the presence and extent of this inferior metabolic and physiological development, the number of such children appears to vary widely in different localities. In Birmingham, for example, "delicate" children are assessed at 6 per 1000 of the school population, in Manchester at 17·2, in London at 24·5, and in Cumberland at 0·7, and even the higher figures probably represent but a fraction of the total number of school-children whose health is below normal. Detection and treatment of actual abnormality—e.g., of vision, teeth, or hearing, however necessary they may be, are hardly within the province of preventive medicine, which stands for a knowledge of the factors influencing the metabolic processes of growth and nutrition and an ability to recognise early departure from the normal or even the tendency to departure. Apart from congenital and acquired defects the pathological processes that affect children seem to be comparatively few in number, but the sensitiveness of the young child's nervous system is such as to make functional derangements extremely common, and it is the study of these which should reveal types of aberration or diathesis and so bring us in the end to a realisation of causal factors.

It may at present be impossible to differentiate exactly any one diathesis from another; this does not discourage Sir GEORGE NEWMAN, who believes that symptomatic study even now affords broad and helpful indications for practice. Overlapping and ill-defined as they are, he recognises two common types of ill-balanced children: (1) The catarrhal child, in whom there is a tendency towards hypertrophy of the lymphoid tissue and a special susceptibility to inflammatory exudation from mucous surfaces. This child may be either thin and irritable or fat and phlegmatic, he has a tendency to seborrhœa or urticaria, shows irregular furred areas on the tongue, eczematous patches or fissures on the skin, and catarrh of the mucous membranes. (2) The neuropathic child, who shows a lack in nervous regulation of the whole body with atony of the muscles, the weight of the body being balanced by stance rather than by muscular action. This child is pale and thin with round shoulders and excessive lumbar curve. His aspect at rest is listless and apathetic, but he is excitable, impressionable, and sensitive, liable to habit spasm, to headaches, and unexplained pyrexia. Inadequacy whether of nutritional processes or of muscular and nervous control are without question the precursors of much definite ill-health and invalidism, yet the clinical assessment of such children is a matter of great difficulty, for we have no reliable methods for estimating their physical condition by reference to a norm. The commonly employed ratio of weight to height varies in normal children so widely as to be unserviceable for the detection of subnormality in the individual. The child's general physical and mental condition can only be assessed after the closest observation by an experienced clinician of minor inequalities of growth and condition. Where any aberration from the normal is found Sir GEORGE NEWMAN makes the very practical suggestion that the child should be arraigned in the mind of the examiner under the following catechism:—

1. Is the debility due to *general nurtural neglect* in the child's home—insufficient sleep, inadequate and irregular meals, or vitiated atmosphere?

2. Is the debility the manifestation of some particular *disease* such as tuberculosis, rheumatism, or rickets?

3. Is it the *after-effect* of recent illness, measles, or broncho-pneumonia?

4. Is it an *early sign* of some oncoming disease?

5. Is it due primarily not to bodily disease, but to *neuropathic* or psychopathic disease?

It is along such lines that causal factors will be elicited and insight gained into the part played by heredity, postnatal disease and nurture, whether the latter be faulty in respect of insanitary surroundings, improper feeding, unhygienic living, insufficiency of sleep, or the comprehensive neglect of incompetent motherhood.

Whatever may be the final verdict on the causation of physical defect in childhood it is the earliest years preceding school-life, in which the child is being moulded within the limits of heredity, that bear the brunt of responsibility. It is at this time that the child is most susceptible to the influence of environment, favourable or the reverse, and infectious and infective diseases leave the gravest sequelæ. Medical officers who have carried out continuous supervision of children from prenatal existence to school age all agree that the incidence of defects in such supervised children is far less than in the comparable controls. Much of the school medical work is only necessary because mental and physical nurture began too late. It is both expedient and economical for us, Sir GEORGE NEWMAN writes, to do the most we can for the young child from birth to school age. To this end he advocates extension of the maternity and child welfare scheme and its coördination with the school medical service by opening and extending nursery schools, whose chief functions should be the physical and social welfare of the child, coupled with sensory and motor training along the broadest educational lines.

THE TOXÆMIAS OF PREGNANCY.

A CLINICAL and biochemical study of the toxæmias of pregnancy has appeared this week in the shape of a report[1] to the Medical Research Council from the Research Department of the Glasgow Royal Maternity and Women's Hospital by J. N. CRUICKSHANK, J. HEWITT, and K. L. COUPER. It is based on the record of 200 cases of albuminuria during the second half of pregnancy (excluding albuminuria due to infection of the urinary tract) in all of which a full clinical examination and study of the chemistry of the blood and urine was made. Forty-two other cases of normal pregnancy were investigated in the same way to serve as controls, and the general object was to check and evaluate the changes and reactions in the blood and urine which have been supposed to characterise these toxic states or to indicate disordered function. Though the increasing application of biochemical methods to clinical medicine has raised expectations of rapid advance in the early detection and differentiation of toxic states in pregnancy, such expectations are not realised in this laborious investigation. The results obtained are negative rather than positive, and many biochemical changes, whose diagnostic or prognostic value has been alleged, are shown to be unreliable guides. The report is particularly emphatic on reputed tests of hepatic function, and the statement is made that "not one of them seems to be of practical use in the diagnosis or prognosis of cases of toxæmia." Evidence of impairment of the function of the liver was found in some of the normal controls—more than is usually suspected in normal pregnancy—and there was apparently no correspondence in the abnormal cases between the results of the tests of hepatic function and the severity of the symptoms. This conclusion is of considerable clinical importance as some of these tests have been advocated as affording definite indications for the termination of pregnancy in cases of albuminuria.

As the research was approached from the clinical side the classification in use in the Glasgow Maternity Hospital was adopted, four groups being differentiated. These are albuminuria without toxic symptoms, albuminuria with toxic symptoms (pre-eclampsia), eclampsia, and nephritic toxæmia. Whilst the first three, from the clinical standpoint, seem to form a series in which the same type of toxæmia is seen in increasingly severe degree, a more definitely renal factor is considered to be present in the nephritic type. It is of practical importance to differentiate those cases in which the danger to be feared is immediate—i.e., eclamptic convulsions—from those in which the risk is the more remote one of permanent damage to the kidney; hence the portions of the report that will be found of particular interest to those engaged in obstetric practice are those analysing the symptoms in the various types, such as the correlation of the blood pressure with the degree of albuminuria. In the nephritic group the outstanding difference was a tendency to a slow fall from, or a maintenance of, the original level of the blood pressure in cases in which it was raised, and a similar behaviour of the albuminuria when the amount of albumin was high. Sometimes the degree of albuminuria was raised out of all proportion to the severity of other symptoms. Another feature of this group was that the amount of albumin in the urine was very variable, the variations being independent of the general level of albuminuria. In the other groups, on the other hand, the rise or fall in the amount of albumin was more or less continuous and did not show the same daily variations.

A special study was made of the power to excrete chlorides in view of HARDING and VAN WYCK's assertion that interference with the excretion of chlorides is a characteristic of the toxæmias of pregnancy. These writers also say that it is essential to withdraw all chlorides from the diet. As no ill-effects were observed when increasing doses of salt were given to patients who were recovering on a routine treatment, the conclusion is reached that the views of HARDING and VAN WYCK are incorrect. There are many other matters of interest in this report and not the least are those embodied in the second part of the appendix on the relative incidence of the various forms of toxæmia in a series of 23,630 cases admitted to the Glasgow Maternity Hospital in the ten years 1913–22.

THE GENERAL MEDICAL COUNCIL AND INCOME-TAX.

IT seems rather hard that the General Medical Council, a body created by statute for the performance of certain official functions in relation to the medical profession, should have to pay income-tax as though it were a mere commercial undertaking. Its statutory functions are the supervising, inspecting, and reporting upon medical studies and examinations, the preparation, revision, and issue of the British Pharmacopœia, the registration of qualified practitioners, and the judicial investigation of complaints against them. Towards the cost of performing these duties and the necessary secretariat and office expenses the General Medical Council receives income from registration fees, dividends on investments, and profits on the sale of publications. It had been contended for the Council that its statutory purpose is a charitable purpose—since it is for the benefit of the public that there should be an authoritative list of good doctors and an authoritative list of proper drugs—that the Council exists for that purpose only, and applies its income for that purpose only, and that it should therefore be exempt from income-tax as being a charity. Mr. Justice ROWLATT, however, held that the Council's funds are liable to income-tax assessment. He could see no signs of a trust for the improvement of the practice of medicine; the fact that Parliament has given the Council certain duties which are for the good of the public does not make the Council a charity. To be a charitable body a body must be a charity within the statute 43 Eliz. cap. 4, or must be analogous to bodies which are within that statute. Societies for the benefit of professions or trades are not societies with charitable objects within the meaning of the income-tax law. The General Medical Council, said the judge, is not exactly such a society; its object is to benefit the public rather than the profession; it is only because the public knows that it is protected from bad doctors that the good doctors are benefited. The Council is carrying out statutory duties for the benefit of the public undoubtedly, but Parliament imposes duties for the benefit of the public upon all sorts of bodies and these bodies cannot all be charities. In short, the Council stands outside the statute of Elizabeth and so must pay.

EXHIBITION AT MIDDLESEX HOSPITAL.—On Thursday, Dec. 15th, from 8.30 till 11 P.M., a scientific exhibition and demonstration will be held in the research departments and laboratories of the Middlesex Hospital and medical school.

Annotations.

"Ne quid nimis."

THE PREVENTION OF DIPHTHERIA.

IN London diphtheria has a higher incidence and mortality than in almost any other European capital, and there seems to be no reason for supposing that its ravages will diminish under present conditions. This fact makes it necessary for the responsible authorities to give careful consideration to the modern methods of controlling the disease. In a preface to Dr. Graham Forbes's recent report the Medical Research Council say that "the large body of evidence already available leaves no doubt that the disease and its often fatal consequences may now fairly be called avoidable"; whilst Sir George Newman, in his report to the Ministry of Health for 1925, stated that "as antitoxin has proved itself the best method of treatment, so immunisation appears to be our best prophylactic." It is not surprising, therefore, that the London County Council should have decided to re-examine the need for taking fresh measures to combat diphtheria, and it would be regrettable if incomplete accounts of their Health Committee's report should give rise to an impression that they are opposed to the active immunisation of school-children. This report was presented on Nov. 29th, and those who study its full text, as given in the *Medical Officer* for Dec. 3rd, will see that the Committee are by no means against Schick-testing and immunisation, though they feel that more evidence is wanted before these measures are applied to the school-children of London as a whole. They point out that there is as yet insufficient evidence to demonstrate their effect on the incidence of diphtheria in any given community in which the whole or the great majority of the child population has been protected; for though in New York City over 600,000 children were tested and over 400,000 immunised between 1916 and 1926, the total number of children of school age is about 1,650,000, and the fact that until this year the disease has been steadily diminishing cannot with certainty be attributed to the use of toxin-antitoxin. On the other hand, the Committee point out that "according to authoritative American observers, as a result of observation over periods ranging from three to six years, no child who received the full immunising course, and had given a Schick-negative reaction, subsequently contracted diphtheria."

Defence of the community against diphtheria does not imply protection of school-children alone, for, as the report remarks, the disease has its most fatal consequences on those who are less than 5 years old and have not yet come under the educational supervision of the London County Council. It is, moreover, the metropolitan boroughs, rather than the county authority, that are primarily responsible for measures to prevent infectious disease. In the City of Westminster and eight other boroughs, with a total population of a million and a half, preventive schemes are already in operation or are sanctioned. The extent to which these are used must depend largely on those who recommend immunisation to the public, as was emphasised at the meeting which we report on p. 1274, and the Council's Health Committee obviously believe that local education, propaganda, and experiment are what is needed at the present time. "It would appear desirable," they say, "that all public health bodies, both voluntary and public, including hospitals, provided they are persuaded as to the soundness of the measure, should assist the borough councils, as far as possible, by the dissemination of authoritative information on the subject."

Although it is considered premature for the County Council to introduce any measure of active immunisation among school-children until further experience is gained, there is apparently no objection to using the school organisation as a means of spreading information to parents who desire to be informed on the subject. In Holborn, Deptford, and Camberwell leaflets prepared by the borough medical officer of health are distributed through the schools, and these facilities will be extended to any other metropolitan boroughs which wish to adopt the same methods. The report recommends "that those parents who desire that their children should be protected by immunisation should be given every opportunity of satisfying their wishes." In conclusion, we may point out that the Council are responsible for a school population of well over 600,000 children. Before applying a comparatively novel method on so large a scale they are justified in awaiting evidence of the most definite kind, and although in the Medical Research Council's publication there is cumulative favourable testimony to the benefit of toxin-antitoxin in residential institutions and hospitals, yet the number of school-children immunised in this country—e.g., in Edinburgh and Aberdeen—has been relatively small. Until more is known of the incidence of the disease among the half million immunised children in New York City, no more than tentative deductions can be drawn about the effect of the new methods on the incidence and mortality in a large community.

THE ACTION OF LIGHT ON THE EYE.

THE retinal currents have often been investigated since their discovery many years ago by F. Holmgren, of Upsala, and they are a valuable index of the activity of the retina. They are due, however, to processes taking place in the eye rather than in the optic nerve, and they do not tell us how the results of the retinal activity are transmitted to the brain. During the past two years E. D. Adrian, by recording action-currents with the capilliary electrometer and an amplifying system, has investigated the impulses occurring in various types of peripheral sense-organ, and has found that there is a close agreement in the behaviour of the different kinds of end-organ and in the impulse discharges set up by them. In experiments (with Rachel Matthews), which have recently been recorded,[1] he has broken new ground by using a special sense-organ, the eye of the conger-eel, and recording the discharge of impulses in the optic nerve, and its relation to the electric changes in the retina. The results of this research show that the activity of the optic nerve is in close agreement with that of sensory nerves, although the mechanism of the receptor apparatus of the eye is naturally far more complex than that of the peripheral sense-organs. By means of a capillary electrometer and valve amplifier, the action-currents of impulses in the optic nerve of the eel and frog were recorded when the retina was stimulated by light. It was found that the action-currents do not differ appreciably in time relations or in grouping from those in other sensory nerves, and their size is not affected by the strength of the stimulus (all-or-nothing relation). When the eye is illuminated, the discharge of impulses rises rapidly to a maximal frequency and then declines at first rapidly and then more slowly. If the illumination has lasted a second or more there is a renewed outburst of impulses when the light is turned off. Owing to the rapid decline in the discharge with steady illumination, a movement of light and shadow in the visual field is a much more effective stimulus than a steady pattern. When the retinal image does not exceed 1 mm. in diameter, the effects of an increase in the size of the image are the same as those of an increased intensity of illumination. Both the latent period and the maximum frequency of the discharge are determined approximately by the quantity of light in unit time, and the frequency is not directly proportional to the area of the retinal image. The relation between area and threshold intensity for the human eye is of the same kind. When the retinal current and the optic nerve discharge are compared, it is found that the initial

[1] Jour. of Physiology, Sept. 9th.

negative reflection of the retinal response occurs at a fixed interval before the beginning of the optic nerve discharge. This "retinal-nerve" interval has an average value of 0·1 second in the eel. The constant "retinal-nerve" interval is probably due to time lost in conduction through the synapses of the retina. When the light is turned off, there is a constant interval between the beginning of the positive retinal response and the "off" discharge in the optic nerve. The parallel effects of an increase of area and an increase of intensity can be explained by assuming a spread of the excitatory process into regions surrounding the illuminated area. This agrees with the fact that it is impossible to confine the discharge to a single fibre of the optic nerve by limiting the size of the image. In a 2–4 lb. conger-eel the optic nerve is 1½–2 cm. long and about 0·5 mm. in diameter. There are large nerve-fibres in the middle and small fibres round the periphery. In a section with a total of 8000 nerve-fibres there are about 6000 small fibres and 2000 large ones. The average number of fibres in the optic nerve of the conger is about 10,000. Owing to the small number of fibres in the optic nerve of the eel and the large retinal area connected with one ganglionic cell, a spread of the excitatory process is not ruled out by the relatively low frequency of the discharge.

THE STATUS OF MENTAL NURSES.

FORTY years ago the asylum attendant was so little removed from the old time "keeper" that she was ignored by the nursing profession and classed with prison warders and policemen. Largely owing to the efforts of the Medico-Psychological Association the status of mental nurses improved, until in the Act of 1919 they were recognised as nurses and included in a supplementary register. The Association sets an examination in mental nursing and awards a certificate of proficiency to successful candidates, and in the great majority of mental hospitals nurses are expected to obtain this. The General Nursing Council, however, sets another examination for mental nurses, and will not admit to the State registers holders of the M.P.A. certificate alone. The G.N.C. examination has been criticised as being too costly and setting too high a standard in general nursing for those who only wish to register as mental nurses. On the other hand, under the Association's syllabus, the training of the mental nurse has been considered deficient in practical bedside nursing. The fact remains that very few nurses in county and city mental hospitals sit for the G.N.C. examination, and their medical superintendents and committees are fully satisfied if they hold the M.P.A. certificate. There is, however, no guarantee that this will continue. During the last three years 3509 mental nurses obtained the Association's certificate, yet only 126 were admitted to the State register. The anomalous situation that has arisen was the subject of discussion at the quarterly meeting of the Medico-Psychological Association on Nov. 17th, when Prof. G. M. Robertson proposed as a resolution :—

"Arising out of the Report of the Royal Commission on Lunacy and Mental Disorders (p. 107, para. 102) and in accordance with the recommendation of the report of the Parliamentary Committee of Enquiry into Nursing, it is resolved that the Royal Medico-Psychological Association makes every endeavour, by negotiation or, failing that, by obtaining the insertion of a provision in any new Lunacy Bill, to secure that the possession of the Certificate of Proficiency in Mental Nursing of the Association entitles the holders thereof (both present and future) to be registered, on payment of the fees, in the Mental Section of the Registers of Nurses of the General Nursing Councils, and to enjoy all the privileges of registered mental nurses; this to be without prejudice to any examination in mental nursing which the General Nursing Councils may think fit to hold, and to be subject in the future to such supervision and standard as the General Nursing Councils may think fit to impose, as in the analogous case of the General Medical Council and medical professional examinations."

While disclaiming any wish to interfere with th prerogatives of the General Nursing Council, Pro Robertson said that he felt it was not wise tha nurses holding the M.P.A. certificate should b excluded from the State registers. A joint Advisor Council of the M.P.A. and the Mental Nursing Com mittee of the G.N.C. ensures practical identity i training and standards between the two bodies, an as Prof. Robertson claimed, mental nursing demand quite as fine (if not finer) mental and moral qualitie as general hospital nursing. He was sure that th Association had no intention of giving up its cert ficate, which he characterised as the greatest piec of work done for the care of the insane during th last 50 years. The policy of the Association, sai Lieut.-Colonel J. R. Lord in supporting the resolu tion, was to coöperate with the General Nursin Councils in the nomination of examiners and th establishment of the syllabus for their mental nursir certificate, and to encourage all mental nurses t secure registration. The brunt of their exclusio from the register, he continued, fell on the priva mental nurses who were kept out of all the princip nursing agencies and coöperations. Under the ne Bill for the registration of nursing homes they wi also be excluded from employment in these home In Colonel Lord's opinion the Association owed it t mental nurses that their proficiency certificate shou carry with it admission to the State registers, ar since much of the work was voluntary it could co duct the examinations more economically than th State could do. He went so far as to declare tha common sense demanded the acceptance of th coöperation offered by the Association to the Gener Nursing Council. Several speakers in the ensuin discussion felt that Prof. Robertson's proposal offere the only reasonable way out of a difficult positio Opposition, led by Dr. J. K. Henderson and D Wolseley Lewis, was based on a difference of opinio as to which method would best increase the stat and advance the interests of the mental nurse. D Henderson preferred the system advanced by th G.N.C., and called on the Association to put asi the sentiment attaching to its past admirable wo and to march loyally with the times. Dr. Lew said that 63 per cent. of the candidates from h hospital were successful in the first examination the G.N.C. Dr. Bedford Pierce took the point view that the nurses were to be compared with th growing child; in the past they had been under th tutelage of the Association, but the time had con when they might be left to go their own way, and was not seemly for the Association to legislate f them without consulting them. Prof. Robertson, replying, agreed that nurses should have bett representation on the Educational Committee of th Medico-Psychological Association. He felt, howeve that mental nurses were better off under the contr of doctors than of their fellow-nurses, who still tend to despise them. He carried his resolution by a lar majority, and the future therefore hangs on th reply of the General Nursing Council to the offer coöperation made to them.

HEPATIC DISTURBANCE AND MIGRAINE.

WHEN all the well-known causes of migraine, which eyestrain may be cited as the commones have been excluded, there remains a large grou of sufferers in whom the pathogenesis of the disea is obscure. Evidence has accumulated in rece years showing that in many such the failure of th liver to carry out its normal detoxicating functio may be the explanation of the disorder. We recent published a paper by Dr. C. H. Rook in which h reported[1] the favourable results of treatment in number of cases where this hypothesis had serv as the basis for his therapy, and a recent communic tion by Dr. J. S. Diamond lends further suppo to the theory.[2] Working on the 35 cases in who

[1] THE LANCET, 1927, i., 705.
[2] Amer. Jour. Med. Sci., 1927, clxxiv., 695.

other causes of migraine had been eliminated, he found evidence of disturbed liver function in more than 90 per cent. The tests employed were the van den Bergh reaction and estimation of the urobilinogen of the urine. The cases were divided into three groups: in the first, there was hemicranial headache with digestive disturbance; in the second group of 15 cases this headache was associated with nausea and vomiting, the classical "bilious attacks"; in the remaining eight cases the abdominal symptoms were predominant and often severe, simulating organic disease of the biliary tract, although neither cholecystography nor laparotomy in five cases revealed any evidence of organic disease. The predominance of females over males and the presence of a family history of migraine were apparent in the whole series in typical manner. In 91 per cent. of the whole series the van den Bergh reaction showed a latent icterus with a bilirubin retention of from 3 to 5 units, the normal being 0·8 units or less. The urobilinogen was similarly increased from 1–35 up to 1–200 in the most extreme cases. It is suggested that this evidence points strongly to hepatic dysfunction. The explanation put forward by Diamond is that the failure of the liver leads to the passage of toxic putrefactive substances from the portal into the general circulation, by means of which vascular changes are produced in the cerebrum or other viscera, all possibly of an anaphylactic nature. The treatment deduced is the withdrawal of animal proteins and the adoption of a strict lacto-vegetarian diet, lacto-dextrin and various sour milks being added with a view to changing the intestinal flora. The occasional use of cholagogues is advocated as an aid to biliary secretion. The favourable results reported by Rook in the paper to which reference has already been made give a hint that drastic dietetic measures are not always wise; Diamond's observations on bilirubin retention, however, may indicate that we are approaching the solution of a problem of great practical importance, even if migraine is sometimes classed amongst the minor maladies by those who do not suffer from it.

POST-VACCINAL ENCEPHALITIS IN HOLLAND.

IN a recent issue of the leading Dutch medical journal Dr. J. T. Terburgh,[1] the medical officer of health at The Hague, deals with the occurrence in Holland of encephalitis after vaccination, to which we have drawn attention on previous occasions.[2] Since his previous communication to the same journal, made in collaboration with Dr. F. S. van Bouwdyk Bastiaanse and Dr. Bijl, Dr. Terburgh has collected a total of 124 cases of "post-vaccinal encephalitis" which have occurred in Holland. He remarks that though this number is regrettably high, the total is small in view of the large number of vaccinations performed in the country. The first of the 124 cases occurred in June, 1923. During 1924, up to August 1st, four more cases were reported, two of which had been vaccinated in March and one in July, while the date of the fourth child's vaccination was not known. Of these five cases, two died. In the following triennium, extending from August 1st, 1924, to August 1st, 1927, there were 119 cases of encephalitis following vaccination in Holland, with 36 deaths. The number of cases in each of these years was 38, 29, and 52, with 15, 4, and 13 deaths respectively. There was thus a fall in the mortality from 40 per cent. to 25 per cent., the average mortality of all the cases being 30 per cent. An explanation of this fall in the mortality during the last three years is that the medical profession began to pay more attention to encephalitis occurring after vaccination, so that more mild cases were notified to the public health authorities. There was a considerable variation in the total number of cases notified each month. While March headed the list with 44 cases, not a single case was notified in November and December, although 70,164 vaccinations were performed in these two months, and there was a considerable irregularity in the number of cases notified in the other months during the triennium in question. It is noteworthy that a much larger proportion of cases occurred in country districts than in large towns. Thus in districts with less than 5000 inhabitants the incidence was three times greater (32 cases per million inhabitants) than in those with more than 100,000 (11 per million). The number of cases in the various Dutch provinces also showed great variations. While, for instance, the province of Zeeland had 52 cases per million inhabitants, the province of Limburg had only two, although more vaccinations were performed in Limburg than in Zeeland during 1925. A table of the encephalitis cases at various ages shows that only one case occurred in each of the first two years of life, as compared with seven in the third year, 34 in the fourth, 27 in the fifth, 37 in the sixth, 15 in the seventh, and 1 between the seventh and twelfth, while the age of one patient was unstated. Another table shows that cases occurred in only 73 of the 1080 odd urban and rural districts in Holland, and that in 49 of the 73 only a single case was notified as compared with 24 in which there were more than one. The vaccine lymph employed in these cases had been prepared at Amsterdam, Rotterdam, and Groningen respectively. 101 cases occurred after use of the Amsterdam lymph, 16 after the Rotterdam lymph, and 6 after the Groningen lymph. This is equivalent to one case for every 6604, 9257, and 5585 vaccinations respectively. The Amsterdam and Groningen lymph, therefore, seems to have been associated with more cases than the Rotterdam lymph. The reaction on the arm varied considerably in the children affected. In only one instance was it severe, while in many cases a normal or slight reaction was reported. Dr. Terburgh does not believe that post-vaccinal encephalitis is caused by the vaccine virus itself or by organisms that gain entrance to the body simultaneously with the vaccine virus; he inclines to the view, which is also held by Prof. H. Aldershoff, director of the Dutch Serological Institute at Utrecht, that the process of vaccination rouses into activity an unknown dormant virus which is the cause of the encephalitis.

MULE-SPINNERS' CANCER.

WE publish in this number an extract from a report, drawn up by Dr. J. Robertson of Darwen for his health committee, in which he deals with cancer in mule-spinners. Dr. Robertson has conducted a careful inquiry into this condition and has recently published a detailed account of his results.[1] He comes to the conclusion that, contrary to the findings of the Departmental Committee which was appointed to consider this condition, scrotal epithelioma in spinners is not caused by oil sprayed from the working mule and that the faller shaft does not take any part in its causation. He finds the causative factors in a dirty scrotum and mechanical friction from the hard cloth of the overalls, the effect of this friction possibly being aggravated by the dye of the overalls and by the use of an inelastic brace. The factors incriminated by Dr. Robertson are however hypothetical, while certain kinds of oil have been shown to be possessed of carcinogenic action, not only for mice but also for men. The careful observations of Dr. Alex. Scott on the occupation dermatoses of paraffin workers in the Scottish shale oil industry[2] afford abundant evidence that certain oils produce cancer of the skin in man, and that the skin of the scrotum is particularly susceptible to this particular agent. Dr. Scott's observations clearly show that for this form of occupational cancer there are certain definite

[1] Jour. of Industrial Hygiene, 1927, ix., 217.

[2] Eighth Scientific Report of the Imperial Cancer Research Fund, and THE LANCET, 1923, ii., 1370.

sites of election where carcinomatous changes occur most frequently, while there are certain areas of skin which seem to be practically immune against the carcinogenic action of these oils. Of the susceptible sites the scrotum is one, the arm, forearm, and the back of the hands is another, while the leg is remarkably resistant. Obviously this site incidence cannot be explained by friction, nor does it depend entirely on the amount of the carcinogenic agent in play. Dr. Robertson's point, that the oil is not carcinogenic because it does not produce cancer of the feet in mule-spinners although it undoubtedly comes into contact with them, seems to be made without due regard to Dr. Scott's observations. Even though it may be true that in mule-spinners the oil is not sprayed directly on the overalls in the region of the scrotum, it does not follow that no oil reaches the scrotum. The practical importance of this problem is to be found in the legal question whether cancer in mule-spinners is an occupational disease requiring compensation or whether it is due rather to the personal habits of the operator. In view of the outstanding facts that cotton-spinners are exposed to the action of an agent of proved carcinogenic power and that the scrotum is the site of election for this agent, it is difficult to see how the Departmental Committee could have arrived at any other conclusion than that "in the absence of exposure to mineral oils there would be no mule-spinners' cancer."

CINEMATOGRAPHY OF INTESTINAL MOVEMENT.

SINCE Grützner in 1898 introduced mercury into the intestines of animals and observed it with the Rontgen rays, many attempts have been made to apply serial photography to the study of intestinal movements. A recent observer, W. C. Alvarez, of San Francisco, has tried to obtain motion pictures of gastric and intestinal peristalsis. As so many loops of intestine were working at the same time, he found it hard to record what was taking place until the loops were marked by black threads, which enabled their individual movements to be followed. The films showed a series of rhythmic segmental movements taking place in the small intestine, corresponding with the churning movements (*Pendelbewegung* of Ludwig). Sometimes a rush movement takes place in the coils, the upper coils trying to hurry the food down and the lower coils pushing it back (*Rollbewegung* of Nothnagel). It surges backwards and forwards, and finally passes along. A striking phenomenon said to be observed is the invagination of one portion of bowel into another. A coil may be sucked in, then a contraction forms below it and pushes the invaginated coil out again. It is doubtful, however, if this can be regarded as a normal process. The conditions of observation, with open abdomen and exposed intestines, under anæsthesia, are by no means natural, and these invaginations may be compared with the agonal intussusceptions frequently found post mortem, which take place upwards or downwards. Cannon's work, using trained unanæsthetised cats and observing loops of bowel with X rays after ingestion of bismuth meals, probably approaches most closely to the normal. He showed that the activity most common in the small intestine is the segmentation of the food in a coil of intestine, rhythmically repeated and followed by a peristaltic movement of the mass to another coil where segmentation again takes place. He also found the usual movement in the proximal part of the colon to be in antiperistaltic waves driving the food back towards the ileocæcal valve which is usually competent to hold solid or semi-solid food from regurgitation into the small bowel. These antiperistaltic waves are interrupted at intervals by a strong general contraction passing along the cæcum and ascending colon; a moment later antiperistaltic waves begin again. The application of serial photography to man has had to wait for the improvement of apparatus and technical methods; but it has been used by some workers for the past few years, at first for research and later in routine examination to ascertain th presence of arrested peristalsis or the constancy c a filling defect in stomach and bowel. A series c six to ten exposures at intervals of one second ma be made while the patient holds the breath, and th superimposed films enable small rigid areas to b easily differentiated from the remaining mobile wa of the viscus. A warning may be offered, howeve that these elaborations of method are no substitut for the trained observer. In the duodenum, fc instance, a few films taken at various angles are bette for diagnosis than a series in the anterior view while it is still better to take the serial film at a angle showing the lesion in profile.

ANÆSTHESIA IN GOITRE SURGERY.

THE merits of different methods of anæsthesia fc goitre operations were discussed at a recent meetin of the Section of Anæsthetics of the Royal Society c Medicine. Mr. T. P. Dunhill gave a broad-minde review of the question and showed that severa different methods might receive equal support i most cases. His own predilection appeared to be fc endotracheal insufflation in cases in which there wa obstructive dyspnœa, and for local analgesia when th patient was very ill. He described one exceptiona case in which he was satisfied that chloroform was th most desirable anæsthetic to employ and had used i with success. In the vast majority of instance however, he believed that chloroform was best avoide in goitre surgery and in this opinion subsequen speakers concurred. Sir James Berry favoured ligh anæsthesia with open ether for most cases, and lai stress on the importance of the anæsthetist bein familiar with the anatomical peculiarities of th trachea in the deformities brought about by variou kinds of goitre. The inadvisability of starting th anæsthetic anywhere but on the operating table wa pointed out by a later speaker, but this is a poin which Sir James Berry had emphasised at a previou meeting when he said that before a goitre operatio the administration of the anæsthetic should never b begun until the surgeon is absolutely ready to operate This is, of course, because it is never certain that slight or even an indiscernible dyspnœa may no with the induction of anæsthesia rapidly become s grave that immediate operation is essential if respira tion is to continue. Mr. Dunhill had previousl stated that every goitre patient should be X raye before operation and this precaution will reveal thos post-sternal tumours which have in the past often bee responsible for the sudden unexpected onset c dyspnœa in early anæsthesia. The goitre patient one for whom the anæsthetic should always be give by a specially skilled person, and this is more particu larly true of the exophthalmic goitre patient. Thes subjects, when a local analgesic is not suitable c desired, provide some of the most trying problem which the surgeon and anæsthetist are ever calle upon to solve. The psychical and the cardia frailties of the patient render her a peculiarly awkwar individual both for the induction and maintenanc of anæsthesia and for safe and thorough operativ measures.

WEIGHT AND SIZE OF BRAIN.

THE Vienna school is responsible for much detaile work on the comparative weight of the human brai according to sex, age, and other factors. It was found for instance, that the brain of the suicide exceede the average by 100 g. Many years, however, hav gone since it was thought that the weight and size c the brain could be taken as an index of the intelligenc of its owner during life. Anyone still holding th primitive view was bound to find his opinion modifie on consideration of the high association areas c Flechsig, those regions which were shown by him t be the last to myelinate. The idea of association put the mere mass of the cerebral elements in a secondar position, and makes of much greater account th

ntelligent use of a relatively smaller quantity by ombination and association between its parts. It is f interest in this connexion to recall the fact that the rain of Neanderthal man was probably larger than any modern brains, but that the primitive human rain was weak in those very regions which, in us, are ne last to myelinate. There can be little doubt, from ny point of view, that Neanderthal man possessed very intelligent brain, but it was lacking in those ider horizons which opened to his successors with ne further development of their higher association echanisms. Recognising this fact, that quality ther than quantity is the important matter, the natomist is nevertheless right in recording the eight and external appearance of such brains as me within his observation; this, in many cases, cludes nearly all that he can observe on his dead aterial, although he may assume many other things om his estimates of proportionate developments, nd so on. Thus such measurements as Dr. Bernard ollander gives, in his letter in our present issue, are ite in order as formal records, made without any ggestion of close correlation between size and ental capacity. It must be admitted that the value, hatever it may be, of such records is impaired in any cases, as Dr. Hollander says, by untoward clusions, to guard against which calls for care in e future. When he states that it is time we began learn something about the varied functions of the rts of the brain already mapped out by anatomical search, it is only fair to point out that this is being ne. The attack is being carried on directly and directly, largely by undermining from below. natomical criteria cannot be satisfied by mere ychological speculation, but demand structural and perimental correlation. Caution would seem justible in placing the seat of the higher intellectual nctions in any particular region of the brain, for it pears reasonable to expect that all parts would have contribute if association is to be at its best. The ellectual impairment which accompanies the ernicke type of aphasia, for instance, without any ntal lesion, is an example of such an interruption. e investigation is, naturally, of highly complex and ficult sort, but in time the various anatomical risions of the brain will doubtless be fitted with some, not all, of their corresponding functions.

LEISHMANIA DONOVANI IN THE SKIN.

AMONG lower animals a variety of Chinese field use, *Cricetulus griseus*, has alone been found sceptible to direct inoculation with kala-azar. recent experiments [1] on this hamster Dr. C. R. sh and Dr. C. H. Hu, of Peking Union Medical llege, showed that it is the cells of the reticuloelothelial system that contain the kala-azar paraes. These cells filled with Leishman-Donovan bodies formed the characteristic lesions of the disease. e clasmocytes (phagocytic wandering cells) of the n, subcutaneous and areolar tissues, were much reased in number and filled with kala-azar bodies; y formed a thick layer of heavily infected tissues ering the animal, though on the external surface he body, after removal of hair, no changes could seen. This finding led these investigators to ewed search of necropsy material from their human es of kala-azar, in none of which had studies of the n been made, and the results were interesting and portant.[2] From one body a small piece of skin from another some subcutaneous tissue was vered, though it could not be ascertained what been the appearance of the skin, or from what of the body the bits had been derived. In both ies typical lesions of kala-azar had been found oughout the viscera, and in the rescued necropsy ments sections revealed many clasmocytes filled n Leishman-Donovan bodies, exactly as they had n found in all the inoculated hamsters; that is, all levels of skin below the corium contained the infected cells, which were collected in masses about sweat glands and arterioles and scattered throughout the corium and into the papillæ just below the epidermis. The lesions were qualitatively like those seen in the oriental sore of *Leishmania tropica*, though less extensive, and a closer relationship between the two diseases is thus established. Though the skin in kala-azar shows areas of dark pigmentation, no characteristic changes have been described, but the skin in these patients has not yet been well studied histologically. The perivascular arrangement, in the skin, of the cells containing Leishman-Donovan bodies makes it very likely that a blood-sucking insect would imbibe the parasites from patients with kala-azar, and the question is now raised whether the Leishman-Donovan bodies described in the peripheral blood really existed there, or only escaped through the wound in the skin along with the blood. In the hamsters some of the parasites probably existed in the peripheral blood, for the few seen in blood films were usually within polymorphonuclear neutrophilic leucocytes. (The record of a case of congenital human kala-azar by Dr. G. C. Low and Dr. W. E. Cooke[3] makes the presence of Leishman-Donovan bodies in the circulating blood highly probable.) It is of immediate practical importance that, if these skin lesions are present constantly in kala-azar, histological examination of the skin may be used as a diagnostic procedure instead of, or supplementary to, punctures of liver and spleen.

AN INDUSTRIAL MUSEUM.

THE Home Office is to be congratulated upon the organisation of a museum—the first of its kind in this country—which is designed to show the methods, arrangements, and appliances which have been devised to promote the safety, health, and welfare of industrial workers in the manufacturing and other industries coming within the sphere of its administration. Situated at Horseferry-road, Westminster, it occupies a floor space of 10,000 square feet and embraces a Safety Section, consisting of machines and appliances, as they would be installed or used in a factory, photographs and models; a Health Section; and a Welfare Section. In many cases the safety devices are contrasted with machinery and apparatus which are dangerous to the worker. In the first section ingenious devices are shown by which the machines are automatically stopped when the limbs of the worker are in danger of injury, or by which the machine refuses to function unless it is worked in a proper manner, or by which the worker's hands are automatically thrown away from the danger area on an emergency. There are other devices for enclosing the dangerous parts of the machine in cages, or within shields, so that the workers cannot come into contact with such parts, and the fertility displayed by the inventors is surprising. In the sections devoted to the preservation and conservation of health industrial diseases come first, and the exhibit includes photographs in illustration of lead poisoning, silicosis, and the various dermatoses, including epitheliomatous ulceration, to which workmen in special directions are liable. Charts also illustrate the incidence of disease in various industries over a period of years, and models show the lesions produced by disease, while there are microphotographs of lung lesions produced by inhaling industrial dust, and an important series of X ray pictures of the lung. Anthrax and its dangers are depicted by an interesting exhibit prepared by the director of the Home Office Anthrax Disinfecting Station at Liverpool, comparing disinfected and undisinfected wools at various stages of the manufacturing process. The advantages of proper lighting and efficient ventilation are demonstrated by much ingenious apparatus, and ample space is devoted to welfare work. There are model rest-rooms, canteens, and examples of how first-aid should be made available and ambulances be fitted up. The furniture,

[3] THE LANCET, 1926, ii., 1209.

utensils, and appliances for the proper equipment of all these can be seen, as well as examples of protective clothing.

It is intended to keep the museum up to date, so that it shall always exhibit the latest and best methods of promoting the safety and health of industrial workers. Last week the King and Queen paid a visit to the museum, which is now open to the public in the mornings of week-days and on Saturday afternoons, while at other times parties of visitors can see the museum by arrangement. While serving as a useful means of education to employers, employed, inspectors of factories, and welfare workers, and while helping designers to keep in touch with modern machinery, the museum will also give valuable information to medical practitioners and students, brought together in a compact form. Diffusion of knowledge of the highest practical value should follow this wise movement of the Home Office.

A LUNCHEON was held at the Savoy Hotel on Tuesday, Nov. 29th, the occasion being to make a public appeal for the funds of the Hampstead General Hospital. The hon. treasurer of the hospital, Mr. Howard Figgis, was in the chair, and the appeal was definitely stated to be for £20,000, a large proportion being for debts incurred. A letter from A. A. Milne was circulated, pleading wittily for small as well as for large subscriptions, and setting out the interesting point that the out-patient department of the hospital, which now stands in Bayham-street, Camden Town, is on the site where Charles Dickens lived as a boy, when his father first came to London with Mr. Micawber's expectancy that "something would turn up." The guests were also furnished with a statement that the hospital had treated nearly 2000 in-patients in the past 12 months, and that in addition to the payment of its debts, another operating theatre was urgently required as well as an emergency block for cases needing immediate surgical treatment. Thus an increase in annual subscriptions to the amount of £5000 was called for as well as a capital sum. The Bishop of Willesden supported the Chairman's appeal, and was followed by Mr. Bransby Williams, the owner of part of the premises in Bayham-street where Dickens had occupied an attic. Mr. Williams spoke of his intention to give one-man shows in aid of the appeal, and in particular of hoping to arrange an all-star programme of a Dickens play. No one need be reminded that of all English men of letters Dickens would have been the readiest himself to support the appeal. Of the 80,000 out-patients who attended the Hampstead General Hospital last year we may be certain that a large number in that poor and populous neighbourhood belonged to the type whose pathetic struggles and persistent courage and good humour made such splendid material for his romances.

EPSOM COLLEGE.—The Council of the College is about to award a St. Anne's Home Scholarship of £52 a year to the orphan daughter of a medical man who was in independent practice in England or Wales for not less than five years. Candidates must be fully 7 years of age and not over 12 years on May 1st, 1928. Forms of application can be obtained from the Secretary at the office of the College, 49, Bedford-square, London, W.C. 1.

OFFENSIVE GASES IN INDUSTRY.—By the Public Health (Smoke Abatement) Act, 1926, power is given to the Minister of Health to make orders extending the provisions of the Alkali, &c., Works Regulation Act, 1906. A draft order has been prepared extending the list of noxious or offensive gases mentioned in that Act, and extending the list of scheduled works requiring registration. Copies of this order may be seen at the offices of the Ministry of Health, Whitehall, London, S.W. 1, or may be obtained from H.M. Stationery Office, at Adastral House, Kingsway, London, W.C. 2; at York-street, Manchester; or at 1, St. Andrew's-crescent, Cardiff. A public inquiry will be held into the subject matter of the draft order by Dr. T. L. Bailey, at the offices of the Ministry of Health, Whitehall, London, S.W. 1, on Wednesday, Dec. 14th, at 11 A.M. Any person interested may attend and give evidence.

Modern Technique in Treatmen

A Series of Special Articles, contributed by invitati on the Treatment of Medical and Surgical Conditio

CCLIII.

TREATMENT OF CONGENITAL STENOSIS OF THE URINARY MEATUS.

(PIN-HOLE MEATUS).

THIS condition receives little notice either in text-books or teaching of surgery, but it is qu familiar to those whose work is largely with childr and is indeed the most frequent cause of dysuria male infants. It is important to be able to recogn and treat pin-hole meatus because it is often ov looked and the troublesome or even danger symptoms which it occasions are wrongly attribu to other causes. Treatment is nearly always succes and should be undertaken at the earliest possi moment.

Ætiology.

The stenosis is restricted to the distal extremity the urethra and rarely extends for more than a quar of an inch proximally. It is found in babies a f days old, though diagnosis is commoner in the seco third, and fourth years of life. Congenital stenosis the meatus is a particularly accurate name a exactly describes the condition, though it is diffic to account for it any more satisfactorily than we explain the occurrence of other congenital anoma such as cleft-palate and imperforate anus. Associa congenital defects are rare, but I have seen patient in whom a double ureter and pin-hole mea coexisted. The proximal part of the urethra developed from the urogenital sinus and is appare never involved. The distal part which traverses glans penis is formed by the canalisation of a p of epithelium. Pin-hole meatus is due to an ar of this process before a channel of adequate size been formed, but we cannot tell what determines irregular development.

Signs and Symptoms.

The signs and symptoms are due, in the first pla directly to interference with the outflow of urine, a in the second place to the urinary infection wh often follows it. Dysuria is the commonest sympt and the child's mother will almost always desc straining at micturition, a small and intermitt stream, and frequent crying due to pain or the antici tion of pain. In older children there is often inc tinence of urine or so-called frequency of micturit The bladder becomes distended and the child unable or unwilling to pass urine until an overf incontinence is established and a little urine drib away at a time. If such patients are examined t will be found to have a bladder which is disten sometimes to the umbilicus. Acute retention m occur and the patient may pass nothing for 24 ho This condition will gradually progress into overflow incontinence described above. Stagnati of urine in the bladder is often followed by infect and some of these children will arrive with a diagn of pyuria though the cause of the pyuria may h escaped detection. Another important group symptoms is due to an ulcer at the meatus. I surprising how often the parent will describe t "water-blisters" which form at the urethral ori and "then break to form a sore." This sore or u frequently bleeds, so that hæmaturia may be the complaint. This triad of signs (vesicle, ulcer, bleeding) is probably caused by the irritation of a d of infected urine which is retained proximal to point of stenosis. Possibly the child's efforts to rel pain and obstruction by frequent handling of penis are contributing factors. It will be seen t the signs and symptoms are protean, and it is s wonder that a correct diagnosis is often delayed.

Diagnosis.

The chief difficulty in diagnosing pin-hole meatus is remember that such a condition exists. It is like urvy and retropharyngeal abscess which usually offer obstacle to diagnosis, except the all-sufficient one at other diseases which give a rather similar picture ring first to our minds. If poliomyelitis and osteo-yelitis did not exist we should not forget scurvy, d if phimosis never occurred we should more often ink of pin-hole meatus. There is a tendency for me doctors to think that circumcision is the appro-iate treatment for almost any disease or abnormality the baby's penis, and this operation is often rformed without the careful preliminary examina-on that such patients deserve. It must be emphasised at phimosis per se rarely, if ever, obstructs the tflow of urine and, in the absence of balanitis and raphimosis, circumcision is very unlikely to relieve suria.

A simple examination will reveal the presence of n-hole meatus, but it may often be suspected before e examination is made. The most common com-int is dysuria, and this includes all forms of aining before, during, and after micturition. A ry of urethral bleeding, blisters, sores, bed-wetting, d every kind of incontinence of urine or frequency micturition in a small boy should lead to a careful amination of the meatus before other causes are sidered. In some children a long or tight foreskin mpletely prevents this examination, and circumcision ould then be advised without hesitation. The actice of stretching the foreskin by forceps is not a isfactory substitute for circumcision, because it en damages the delicate tissues and fibrosis may low. It is wise to warn the parents that circum-ion may have to be followed by a second small eration if there is any suspicion of stenosis and the atus is invisible. If there is a clear view of the atus it is usually only necessary to look at it to ide if stenosis is present. It is difficult to define size of the normal orifice in exact terms, but the snosed meatus is generally so like a pin-hole that it easy to make the diagnosis. If there is real doubt ether diminution exceeds normal limits an attempt y be made to pass a sterile probe, but experience kes this rarely necessary. The margin of a normal atus may partially adhere and simulate a minute fice, but this pitfall is avoided if the meatus is mpressed between the finger and thumb in an antero-sterior direction (i.e., in the line of the orifice) every suspected case. This simple test will always w the real size of the orifice. Additional informa-n may be gained by watching the stream of urine; calibre must be observed, as well as any hesitancy nterruption in the act. There may also be incom-te emptying of the bladder, this being estimated the eye and hand rather than by an instrument.

Differential Diagnosis.

The differential diagnosis ought to be easy because re is no other condition which gives quite the ne picture. Over-attention to one sign or symptom y, however, cause mistakes if examination of the nary meatus is omitted. Hæmaturia is a common plaint in pin-hole meatus and the parents often not know that the blood is coming from a meatal r. Hæmaturia from a point higher in the urinary t (e.g., nephritis, calculus, oxaluria, hæmophilia, erculosis, or new growth) should not be confused h it. Enuresis is of many kinds and due to many ses, but it is time enough to fall back on bella-na and good advice when a careful examination disclosed no local lesion and the urine is normal. s well to remember that spina bifida occulta and one in the urethra can produce some of the same ptoms as pin-hole meatus. Dermatitis and other erficial lesions of the penis should be recognised. as been recently suggested [1] that dysuria in male nts is often due to a particular kind of dermatitis. was shown that in certain circumstances urine, which is normal when passed, becomes infected from the alimentary canal by a bacillus which liberates ammonia from the urine-soaked napkin. This ammonia fomentation induces a dermatitis of the napkin area, and this in turn causes dysuria. This condition seems uncommon in England, and one suspects that a little cleanliness is enough to avoid it. Epispadias and hypospadias are easily recognised and phimosis has already been considered.

Complications.

The condition, if untreated, produces a series of back-pressure phenomena which may ultimately involve the pelves of the kidneys. Infection of the urinary tract readily occurs, and it seems possible that hydro- and pyo-nephrosis in children may be sometimes the direct outcome of congenital stenosis of the urinary meatus, though there is little evidence on this point.

Treatment.

Treatment is fortunately simple, but demands careful attention to detail if recurrence is to be avoided. Instrumental dilatation is unsuccessful because it is followed by cicatrisation; it should never be performed without first carrying out the little plastic operation which will be described. Circumcision is an essential preliminary in a few patients, but it has usually been done already, and indeed, the parents often attribute the child's symptoms to the operation irrespective of the reasons which occasioned it. Circumcision has not, of course, caused the stenosis, but the operation does sometimes seem to have been performed in the false hope of relieving the urinary obstruction.

Operation: Meatotomy.—The simplest of plastic operations is sufficient, but a general anæsthetic is required. An injection of atropine (gr. 1/150 for a baby) is administered and the patient anæsthetised with ether. Iodine is applied to the glans penis and a fine scalpel or pointed tenotome is introduced ¼ inch into the urinary meatus. An incision is then made into the inferior surface of the urethra traversing the substance of the glans until its inferior surface is reached. A tapered glass bougie is inserted, and if this does not easily pass to the required distance the incision must be carried a little further up the urethra. Bleeding is negligible, and it is now only necessary to prevent the margins of the incision falling together. This is best done by a fishing-gut stitch on either side which passes from the mucous surface of the incised urethra through the glans and then traverses the corona before being tied on the outside of the glans. These stitches should be removed in about five days. The operation is completed by applying a little iodoform ointment on ribbon gauze.

After-treatment is simple but important. Epithelialisation of the raw surface occurs rapidly, but the enlarged meatus must be prevented from contracting. The patient's mother is given a solid glass rod 4 in. long and 1/5 in. in diameter. One end of this is sharply tapered to 1/12 in. By this means the meatus can be dilated from 1/12 to 1/5 of an inch without passing the rod far into the urethra. The instrument must be boiled before use, smeared with iodoform ointment, and introduced twice daily for six weeks.

A similar condition occasionally occurs in patients suffering from penile hypospadias. There is sometimes a minute orifice on the under surface of the penis, and none upon the glans. It may then be necessary to perform the same kind of plastic operation on the existing meatus before undertaking radical treatment for the hypospadias.

Results.—The results which follow this simple procedure in pin-hole meatus are completely satisfactory and permanent. No special surgical skill or instruments are required, and the operation may be performed by any medical man under the most ordinary conditions.

ERIC I. LLOYD, M.B. Camb., F.R.C.S. Eng.,
Surgeon to the Hospital for Sick Children, Great Ormond-street, and to the Princess Louise Hospital for Children, Kensington.

Special Articles.

GENERAL MEDICAL COUNCIL.

FRIDAY, NOV. 25TH: COMMITTEE BUSINESS.

Progress with the Revisions in the Curriculum.

IN our last issue (p. 1206) we referred to the informatory report on this subject which was laid before the Council by the Chairman of the Education Committee and formally adopted. The Council issued in 1922, under the title of "Resolutions of the Council," a set of some 60 recommendations for the improvement of the curriculum in medicine. In 1925 it directed its Education Committee to inquire into the progress made throughout the country towards the readjustments made in the curriculum in conformity with these recommendations, which are recapitulated in the report of the Education Committee to the Council. The report shows that all the bodies excepting the University of St. Andrews have modified their curricula as a result of the suggestions of the Council. The results may be analysed under three headings: (1) the pre-registration examination; (2) the allocation of three of the five years of the curriculum to the subjects of clinical study; and (3) the stressing of the importance in the curriculum of a number of elements hitherto in many cases regarded as minor subjects and somewhat neglected in consequence; this was done with the object of making the training afforded to the practitioner more complete and more practical than formerly.

The Pre-registration Examination.

This proposal was made with the object of lightening the preliminary portion of the course, and sought to turn to this purpose all the assistance which other educational agencies, and in particular the higher secondary schools, are able to afford in laying the scientific foundation for the course. The Council intended that the medical applications of physics, chemistry, biology, anatomy, and physiology should be studied throughout the distinctly professional part of the course, and that the students' knowledge of these applications should be tested in the final examination. A pass in England for the higher school certificate in the subjects of the pre-registration examination (physics and chemistry), provided it includes a practical test, should be regarded as amply sufficient to satisfy the requirements of the examination in these subjects as defined above. The attainment of the higher school certificate demands one to two years of specialised study after the close of the ordinary secondary school course, and is within the range of the educated youth of 17 to 18 years of age. In Scotland a somewhat similar examination has recently been established as a subject of the higher school leaving certificate. Should a longer preparatory training than formerly be imposed upon the prospective student to enable him to attain these higher certificates, the Council have raised the age for students' registration from 16 to 17 years.

All the bodies have accepted and adopted the pre-registration examination. In most cases teaching for it is provided in the medical school either in special classes, or, as in some of the universities, in the ordinary classes of the faculties of science. The special classes vary much in length; some are restricted to one term; others stretch through two; others, again, extend through the complete year.

The Council did not mean that the requirements of the examination should be satisfied by a pass in theoretical physics and chemistry of the preliminary or matriculation examination in general education. The Council have defined it as being "*in addition to* an approved examination in general education," such as the student passes at the close of his school career and before entering the university. One of the bodies apparently accepts a pass in the matriculation examination in physics and chemistry in place of the pre-registration examination. Another point is th the Council intended that the teaching work to e tested by the theoretical and practical examinati before registration should not be any part of the fi years' medical course, defined as a continuous per of 15 terms from the date of registration. Three bod at least, which still keep up the teaching for the first professional examination during the first p of medical study, and have at the same time adopt a period of pre-registration course, have given defin intimation that they are prepared to antedate commencement of professional study to the time the commencement of the pre-registration work, this means tending to shorten and at the same ti to overload the professional course. On the ot hand, there are many bodies which, while giving p registration courses of study, have at the same ti lengthened their courses as a whole to five and a h or six years of study; this seems to be the case in the Universities of London, Manchester, Oxfo Bristol, and Wales, and possibly in other instan shorter periods have been added to the course. would almost seem as if there were in the minds the teachers in medical schools a distrust of the physi science which is taught in the secondary school, a the great majority of the bodies have provided p registration teaching within the medical school its It may be argued that, if the old first professio examination in chemistry, physics, and biology is s to occupy its position in the earlier part of curriculum, there is much to be said for making instruction on which it is based a continuation o pre-registration course, provided at the same ti that the professional course is not allowed to su in length.

The Length of the Course.

The recommendation of the Council is:—

"The period of professional study between the date registration as a medical student and the date of the fi examination for any diploma which entitles its holder to registered under the Medical Acts should be a period certified study of not less than five academic years, in last three years of which clinical subjects shall be studie"

In Section (*d*) of the "Additional Resolutions" Council has recommended:—

"That the curriculum should be so arranged that minimum period of three years shall in every case be av able for study after the completion by the student of professional examinations in anatomy and physiology h at the close of the second year."

The academic year contains nine months, or th terms of three months each.

The great majority of the bodies have accepted a adopted the recommendation that three years sho be devoted to clinical work after the completion the examinations in anatomy and physiology at close of the second year.

Additional Subjects.

These number about 60, and most of them ha been explicitly included by the great majority of bodies. In some cases the regulations for studen have evidently been hastily drawn up and subje have been omitted. Thus, for instance, many bod have not definitely mentioned that out-patie attendance at the hospitals is required. This particularly noted in the reports of the Irish scho which, as a whole, do not seem to do full justice their rules and regulations to the actual hospital wo Yet it is very probable that in all the Irish scho out-patient attendance is either compulsory or gener Under the heading of anatomy and physiology very f of the bodies use the terms biochemistry and b physics, but give courses of instruction in physiologi chemistry and experimental physiology. A number bodies do not specify either the dissection of the ent body or human embryology; this may possibly an oversight in the prospectus.

In introducing the report as summarised above, Humphry Rolleston remarked that among the vari subjects specially recommended for study by t Council, tuberculosis, venereal diseases, and antena

nditions had appeared to the Committee to be of eat importance, as in modern circumstances the portunities afforded to the student for their study d hitherto been inadequate. They had therefore quested Sir George Newman to prepare a personal port on the whole subject, and this had been culated to the licensing bodies. Another subject ich had especially engaged the attention of the mmittee was the teaching of the administration of æsthetics, a personal report on which, by the late of. H. Littlejohn, had also been circulated.

Examination Committee.

Sir Norman Walker remarked that the report of the amination Committee contained an unusual amount detailed information and was an attempt to broadcast to each licensing body an account of what all the hers were doing. He warned the remaining five porations who were still considering whether they uld combine the examinations in anatomy and ysiology that a recommendation towards that urse might shortly be made, but that the Committee re deferring action until after their next visitation. testified to the cordiality with which the Council's resentatives were received on their visits to the mination rooms of the bodies, the usefulness of the cussions which took place, and the valuable hints t the visitors were able to give to some bodies from at they had seen of the work of others. According he bulletin of the Association of American Medical leges the system worked equally well in the United tes. Commenting on the recommendations of the ncil in 1922 with regard to examinations, he laid ss on that clause which enjoined an interval of e years between the professional examination in tomy and physiology and the final examinations, on that calling for a mark of at least 50 per cent. he clinical examination.

The Registration of Students.

report was presented by Sir Humphry Rolleston n regard to the registration of medical students, ch was adopted by the Council.

ONFERENCE ON SPECIAL SCHOOLS.

PROVISION FOR DEFECTIVE CHILDREN.

iscount BURNHAM, presiding at the first session he Twelfth Biennial Conference of the National cial Schools Union held in London on Nov. 25th, that the work done by special schools in various s of the country was so successful that 80 per c. of their past scholars were now in satisfactory loyment.

ajor I. W. HILLS, M.P., in an address on the r-care of the Physically Defective, quoted the sident of the Board of Education, who had , "Approximately 50,000 children in England Wales are suffering from various forms of pling defects. At most one-quarter of these are resent provided for." This figure did not include blind, the deaf, the tuberculous, or the mentally ctive, to say nothing of the large numbers of ldren classed as "delicate."

iss MARTINEAU (Chairman of the Special Schools mittee, Birmingham), in a paper on the Future of Day Special Schools, said that in 1925 32,975 ldren were reported as mentally defective, of m only about half were receiving education. uncertain policy of the Board of Education on future of these schools was at once a stumbling- k for the local authorities who were under- ng their statutory duties conscientiously, and ncouragement to those who ignored these duties failed to provide facilities for these unfortunate ldren.

r. J. M. GATTI (Chairman of the London County ncil), in opening the afternoon session, traced the d growth in educational training, which together medical inspection, had brought about marked covement of the mental and physical condition of the children, so that the average standards of attainment expected were now much higher than those of 50 years ago. This was all to the good, but it had still to be remembered that it was the external stimuli or environment which brought out the inherent potentialities of the individual.

Young Prisoners.

Dr. J. J. LANDERS (Governor of H.M. Prison for Boys, Wandsworth) gave an address on Crime and Mental Deficiency, in which he quoted Dr. Goring's remark that the one significant physical association with criminality is a generally defective physique, and that the one vital mental constitutional factor in the ætiology of crime is defective intelligence. Dr. Landers went on to point out that "mental age," although an important factor, told nothing of the temperament or emotional stability of the delinquent, which were of prime importance in the cases seen in prison work. Here it was the higher grades of mentally defectives that were met with, and of these the great majority showed marked instability which was greatest during adolescence, and this weakness of emotional equilibrium showed itself in uncontrolled behaviour. Stating that only 5 per cent. of all remands at Wandsworth Prison were considered certifiable under the Mental Deficiency Act, Dr. Landers paid a warm tribute to the socialising effect of the special mental defective schools and to the voluntary associations for the care of the feeble-minded. Every mental defective, he said, was a potential delinquent, and the fact that comparatively few were seen in prison work in London was, he thought, largely attributable to the individual attention paid to the children at special schools, where attempts were made to benefit their health, gain their interest, supervise their progress, and, where possible, find suitable occupations for them after they left.

Dr. F. C. SHRUBSALL (Principal Assistant, Public Health Dept., L.C.C.) said that the education provided by the special schools was necessary to bring out the latent possibilities of the feeble-minded. Mixing with their mental equals, and acquiring or developing the ability to perform simple tasks, established self-respect, confidence, and contentment, and made them amenable to communal life. It was necessary, however, to carry this education on through the trying years of adolescence and to maintain supervision after they left school.

Rheumatic Children.

Dr. A. DINGWALL FORDYCE (Certifying Officer to the Liverpool Education Authority), speaking on Mental Efficiency and the Rheumatic Child, drew attention to the lack of administrative measures for combating rheumatism, a disease which perhaps caused more crippling than any of the other great scourges. He pictured the early rheumatic child as highly strung, often irritable, easily fatigued, unable to take part in continuous work or play, and lacking in appetite. Where parents were well-to-do the environment could be altered to suit this child; medical advice was sought early; diet, clothing, schooling, and rest were all carefully arranged. The child could be removed to a more suitable climate; he was guarded against chills and damp; septic foci were removed at once if they developed, and the child reached maturity organically sound. With the poor child it was otherwise. He was in a milieu which could not be changed, and perhaps he did not come under medical supervision until the damage was done. Though intellectually acute at school he was emotionally unstable and scholastically backward. For such children Dr. Fordyce advocated special residential rheumatic schools, where suitable training and discipline with thorough environmental care and prolonged medical supervision could be arranged.

Dr. J. NAIRN DOBBIE (Assistant Medical Officer, L.C.C.) said that the mentally unstable child was also the physically incoördinated type, and the picture drawn by Dr. Fordyce of the early rheumatic was

that of the "difficult" or neurasthenic child, and it was from this class that not only the rheumatic but also most inefficient children were drawn. Though provision must be made for those who were already the victims of rheumatism, it would be well to look to the preventive side. The present-day treatment of rheumatism was not specific, but was exactly the treatment most authorities advised for the neurasthenic child. To be effective it must begin early, and the child must be removed from the psychical and physical incompatibilities of the poor home or, alternatively, these must be rendered as innocuous as possible. To this end Dr. Dobbie suggested broadening out the maternity and child welfare schemes and bridging the gap between them and the school medical service by providing nursery schools run on open-air lines. The economic value of these steps would be apparent in preventing most of the crippling seen among school-children to-day.

INSURANCE AGAINST THE DOCTOR'S BILL.

WE have already referred [1] to a scheme, instituted by Family Medical Services, Ltd., whereby an insurance policy can be taken out to cover the financial risks of medical service. We have now received full particulars from the managing director, Mr. B. B. Ormerod, of 20, York-street, Manchester. He points out that, unlike food, education, clothing, old age, and the other items of the middle-class budget, the doctor's bill cannot be certainly estimated, and provision therefore cannot be made for it. The "Anchor" policy is designed to meet this difficulty. It applies to all persons between the ages of 2 and 55 not included under the National Health Insurance Act, and the premium works out at from 3½*d.* to 1*s.* 6*d.* per week per member of the family. An average premium for two persons would work out as follows:—

General practitioner's account, up to 5*s.* per visit ..	£1	0	0
Operations, including nursing and incidental expenses up to £50	1	5	0
Specialist consultations	0	9	0
Annual premium	£2	14	0

The insured person carries a primary small charge up to £2 in order to eliminate the trouble and expense of small claims. A family of four people could be insured for all general practitioner's fees over £3 and for operations up to £50 per person for an annual premium of £4 5*s.* 6*d.*, and reductions are allowed as the family increases.

This scheme, the financial security of which rests on backing by underwriters at Lloyds, clearly has advantages over the ordinary sickness policy, under which a man insured for sickness benefit receives the same sum whether he has been three weeks in bed at home with influenza and hardly any expenses, or whether he has spent three weeks in a nursing home after an appendicectomy which cost him anything from £50 to £100. Whilst the "Anchor" policy does not at present provide for requirements like massage, spectacles, dental treatment, inoculations, sanatorium and hospital treatment, the organisers are stated to have these "extras" on the medical bill in mind.

Regular Medical Examination.

Closely allied with the insurance policy is the scheme of periodical medical examination. This was the subject of a deputation to the Minister of Health recently from the People's League of Health,[2] when it was urged that insured persons under the National Health Insurance Act should be regularly overhauled by their panel doctors. The Minister was unable to contemplate such a heavy expenditure to the country at present, but private schemes are likely to find favour with a section of the public. The Regular Medical Examination Associati (1, Princess-street, Manchester, and 1, 2, Gre Winchester-street, London, E.C. 2) offers an assuran scheme for half-yearly examinations of perso not covered by the National Health Insurance, the same financial basis as the policy of Fami Medical Services, Ltd. Although two of the leadi life offices in this country have also associat periodic examination with their policies, it is usua only the father of the family who takes out a l insurance, and, so far as we know, the scheme und review is the only one that attempts to meet t need of mother and children as well. That t policy of regular examination is really practical s suggested by the experience of the Metropolit Life Assurance Co., of New York. Under a scheme examination during the last 14 years the avera duration of life of its members has increased by ni years, whereas the extension of life amongst the gene population during this period was only four and a h years. Of those examined, moreover, no less th 99 per cent. were found to be living in some defecti but easily corrected manner.

The annual premium asked by the Regular Medi Examination Association for a bi-annual medi overhaul is 15*s.* for the first member of the fam and 12*s.* for each additional member. Out of th the doctor is offered a fee of 6*s.* and 5*s.* resp tively on each examination. Should the chos medical man demand a higher fee the Associati will negotiate with the patient, but will not themselv bear a higher charge. Proposers who wish to arran for only one examination during the year will al be encouraged.

MEDICINE AND THE LAW.

Doctors and Detailed Bills.

COMMENT was made in this column some weeks a upon the dictum of a county court judge that a doct is in no more privileged position than a tradesman respect of the duty to furnish a detailed account. decision of the King's Bench Division on Nov. 22 throws further light upon this topic. A partnersh of doctors practising at Maidenhead sued for t payment of 3 guineas fees in the Windsor Cou Court. The defendant (husband of the patie obtained from the Registrar an order for the delive of further and better particulars giving details of t medical attention and advice. The plaintiffs appeal to the county court judge against the order, and reversed his Registrar's direction. Thereupon t defendant made an *ex parte* application to the Hi Court for leave to appeal from the decision of t county court judge. From the statement of coun and the comments of Mr. Justice Salter it appears th the claim for 3 guineas had been supplement by a list of dates and fees; particulars had been giv of seven visits at 10*s.* 6*d.* a visit and gas £1 1*s.*, to £4 14*s.* 6*d.*, which in the claim was reduced to £3 But these details were not what the defendant solicitor) wanted; he sought details of the treatme or advice as well. The patient, it was stated, h suffered from a bad mouth caused by a decayed too The defence was that the doctor gave improper advi and the defendant wanted to know in advance of t trial whether the doctor would state that he h attended the patient for any ailment in addition to t bad mouth. Mr. Justice Salter, giving judgme dismissed the application. "We think," he sa "that the county court judge was right. The bill for 3 guineas; if doctors were called upon, wh sending in their bills, to expand the particulars of ea visit, they could never carry on business."

This common-sense decision is welcome, but it m be remembered that decisions of this kind depend ea upon their own set of facts. This was a county co case, and county court judges rightly do not indu the prolonged skirmishing for position which usua precedes a High Court action and which cau expense and delay. Nor does the High Court ligh

[1] THE LANCET, 1925, ii., 616; and Sept. 17th, p. 615.
[2] THE LANCET, Sept. 17th, p. 615.

terfere with the discretion of the county court in ch matters—least of all upon an *ex parte* application. ıe defendant was not disputing the items in the aim, but was setting up a counter-attack of a fferent nature. Every defendant is entitled to have ch information of a plaintiff's claim as will reasonably able the preparation of a defence; but in this case e High Court evidently thought the defendant was eady sufficiently informed.

Gassed in a Bathroom.

There was an unusual claim in the High Court t week against the Lambeth Borough Council by widow whose husband had been found dead in a th in a house rented from the defendant corpora-n, death having been due to carbon monoxide isoning and drowning. The plaintiff's case was t the gas water-heater had been improperly talled by the corporation, that there was no per ventilation in the bathroom, that the products combustion escaped into the room, and that the endant corporation had given no warning to keep window open when the geyser was in use. The ence denied that there had been any negligence wrongful act on the part of the borough council its servants; it asserted that the water-heater s properly fixed and reasonably safe and proper e taken, that an adequate outlet for waste gases s provided, and that sufficient ventilation was wed for the bathroom; if there was any negli-ce (which was denied), it was pleaded that the eased man had been guilty of contributory negli-ce. Giving evidence for the plaintiff, Dr. Welch, isional surgeon of the Lambeth Division, explained effect of carbon monoxide upon the human body, ing that the victim would be unaware that he being poisoned, the gas being tasteless, odourless, colourless; five minutes' exposure to a mixture ir and 1 per cent. of carbon monoxide would, he l, prove fatal. Evidence for the defence was not rd as the case was settled, the borough council king an *ex gratia* payment of £1000 (£100 to the ow and £300 to each of three children), as well assisting with the plaintiff's costs. There were ious nice questions of law thus left undecided; as doubtful whether the claim would have suc-ded as based on negligence or whether it was a ter of landlord and tenant. It could not be gested that any notice had been given by the nt of the alleged defect in the bathroom. There a further point whether the house could be ribed as unfit for human habitation within the ning of the Housing Act; if the answer had been he affirmative, the plaintiff's claim would have better fortified. It was clearly a satisfactory ng to the case to make a compassionate payment to plaintiff; whatever the legal liability, the circum-ces suggest that detailed and definite explanation ld be given to tenants of the possible danger of g a geyser without adequate ventilation.

Paternity and Blood Tests.

ıe *Times* of Dec. 5th published a message from Munich correspondent describing the use of d tests to determine paternity in the course of minal trial in Württemberg. A woman applying an affiliation order had sworn that a particular was the father of her illegitimate child. Tests made of the blood of the child, the mother, and lleged father, and it is reported that the qualities ıe child's blood bore no resemblance to those r of the man or the woman, but, on the contrary, aled entirely different characteristics. Apparently ourt accepted the results of these tests as proof the paternity of the child must be attributed to other man. It also accepted them as proof the woman had committed perjury, and she was nced to six months' imprisonment.

would be rash to draw conclusions from what is ssarily a brief report. In England Sir Frank old, K.C., aroused interest a year or two ago ating from the bench at Devon Quarter Sessions science might soon supply a sure and simple test in bastardy cases. Judging, however, from discussions at the Medico-Legal Society it would seem possible to be certain only in a limited number of cases—e.g., a child whose blood is found to be Group II could not have sprung from two Group IV parents, or, more generally, the appearance of properties A or B in the offspring when absent in the parents constitutes proof of non-paternity. The *Times* of Dec. 6th stated that the highest Prussian court has pronounced a judgment contrary to that of the Württemberg tribunal. Medical evidence was apparently given to the effect that, out of 2093 blood tests made in 1926, all except one indicated the affinity of blood between child and parent. This one exception, however, rendered the test inconclusive for legal purposes. In our own criminal courts scientific evidence has not always been accepted without reservation. It is recorded that in a trial at Taunton Assizes in 1857 Lord Chief Justice Cockburn expressed considerable doubt of the trustworthiness of scientific evidence differentiating the corpuscles in human blood from those in the blood of an ox, sheep, or pig. He advised the jury not to convict "on this scientific speculation alone." Similarly scientific proof of identification by finger-print seems seldom to be placed before a jury. The police rely upon it in the detection of a criminal, but do not greatly employ it for the purpose of obtaining a conviction.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Chronic Nephritis and the Salt-free Diet.

AT the last medical congress in Paris, which was held in October, there was a long discussion on the various forms of œdema, and the papers read by Profs. Autel, Mauriac, Gowaerts, Vallery-Radot, and Nicaud were among the most important contributions that have been made to our knowledge of this subject. In France Widal's theory has been generally accepted, and the rôle of sodium chloride in the pathogenesis of œdema in Bright's disease has been undisputed until recently. Though nowadays the physiochemical theory has many adherents we remain faithful in practice to Widal's views, and in consequence to the salt-free diet. Daily experience shows that this is superior to a purely milk diet for nephritis with œdema, and that it is also useful in nephrosclerosis without œdema. There is in this no contradiction. The work of Blum of Strasbourg and of Mauriac of Bordeaux has shown that œdema chiefly depends on the retention of sodium, whereas in nephrosclerotics one often finds retention not of sodium, but of chlorine. This explains how the salt-free diet can be useful in the two different forms of renal disease.

The Centenary of Villemin.

We have just been celebrating the centenary of the birth of Villemin, who in 1861 discovered that tubercle was virulent and infectious. What objections were raised against him; yet his discovery triumphed, thanks to the work of Koch, who confirmed his findings. However great was the merit of the German bacteriologist, it cannot be ignored that Villemin's research on virulence had greater importance as regards the history of the pathology of tuberculosis than the discovery of the specific bacillus. His doctrine, for 50 years regarded as the only accurate one, is to-day being challenged, and many specialists are again taking up the ancient theory that the disease is hereditary. Their arguments, based on recent bacteriological research which has shown the multiple forms of the tubercle bacillus, are not without value, and perhaps the heredity theory will again take its place beside the contagion theory.

Treatment of Pernicious Anæmia.

The use of liver for pernicious anæmia is becoming steadily more popular in France, an interesting case being recently reported to the Société Médicale des

Hôpitaux of Paris by Noël Fiessinger and Castéran. The patient had reached a really grave anæmic condition and the size of her spleen made it seem that splenectomy would have to be done almost at once. Liver was given at first in the form of sandwiches, between slices of bread and butter and spread with anchovy. Daily doses of 100 to 250 g. of raw calves' liver were thus administered and the patient went on taking it for four months without break. The result was an increase in the number of red corpuscles and the percentage of hæmoglobin. The size of the spleen diminished and the patient's condition has, in fact, been completely transformed.

Of the diplomas awarded in 1926–27 by the various French universities, 1049 were official, conferring the right to practise, and 112 were the so-called "universitaire" diplomas, which are merely honorary.

An American Medical Organisation has just been formed at Paris by Dr. Joseph Haas, of New York, who will serve as vice-president. The objects of the organisation are to promote scientific advancement and social intercourse, and to provide general and special information for American medical men studying in Paris.

The Académie des Sciences of the Institut de France has awarded three Montyon prizes, of 2500 francs each, to Bensaude, for his work on endoscopy, rectoscopy, and sigmoidoscopy; to Carré, assistant director of the French National Laboratory, for veterinary research; and to Levaditi, for his studies on herpes and zoster. Zoeller received honourable mention for his investigations on diphtheria; the Barbier prize, of 2000 francs, was granted to Leri, for his studies on bones and joints; whilst the two Sergents jointly received the Chaussier prize of 10,000 francs, for their 25 years' work on malaria in Algeria.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Excessive Prescribing.

THE recent appeals of Glasgow doctors from the findings of the Panel and Insurance Committees have now been disposed of, after full inquiry by the Scottish Board of Health. Of the appellants seven lose their case and the surcharges amount to £205, with five guineas expenses in each case. It is disappointing that after 15 years of continuous supervision, criticism, and control of prescribing from the standpoint of the drug fund, there should still be so many cases of real carelessness—for that must be the meaning of it—leading to excess of what has been found reasonable by a body of practitioners like the Panel Committee. There must, however, be a deep root to these anomalies. The medical schools in their teaching take no account of prices and economy of quantities; this is a side of prescribing that is simply not taught. In all conscience the curriculum is heavily loaded already, but when we reflect that this matter of prescribing affects some 16 million of the population of this country it is time that some attention was given at the right stage to the necessity for taking price and utility as well as elegance into account. The Glasgow cases are striking, but they do not stand alone.

Edinburgh Slums.

Edinburgh has opened an inquiry into another big slum clearance scheme. The special part of the scheme now under investigation concerns the St. Leonards ward, which has long been known as one of the most congested sections of the city. The usual statistics have been prepared by the medical officer of health; he shows that infant mortality for the whole city is 88, but for St. Leonards 104, and for all the scheduled areas taken together 132. The death-rate over the group of 15 areas as a whole is 21·9 against 14·4 for the whole city, and it is these unfailing differences of the unhealthy areas that continue to justify the attack on bad housing. No doubt there are other factors than mere house room; but those other factors cannot be handled so long as the house room remains what it is. Statisticians sometimes comment on the fallacious reasons given for the incidence of diseases like tuberculosis and maintain that the lower-class houses necessarily are occupied by the less efficient classes of the population. The doctrine is a comfortable one; but the figures recently produced in Glasgow and those invariably found where slums are tackled seriously, make it quite clear that, whatever be the ultimate causal interpretation, the higher disease- and death-rates are always found where there is overcrowding and the degradations associated with it, and those high rates tend to come down as soon as the populations are transferred to the new houses. This is good enough for practice. In Edinburgh the real battle will begin when the problem of the "Royal Mile" comes to be faced. One hopes that the city will make some serious effort to reconcile modern town-planning with the respect due to Scottish history. Germany in her handsome treatment of the mediæval towns like Rothenberg, Nuremberg, Hildesheim, and ancient Leipzig, to name only a few, has shown by her practice what the ancient cities owe to themselves.

Royal Faculty of Physicians and Surgeons of Glasgow: President's Badge.

On the conclusion of his term of office as President, Mr. R. M. Buchanan presented to the Faculty a badge of office to be worn by the President, and at the November meeting he invested with it his successor, Dr. G. H. Edington.

The badge is in the form of an oval medallion in gold, on the obverse of which are the armorial bearings of the Faculty. The bearings are in enamel of the appropriate heraldic colours. They consist of a shield with, in first and fourth quarters, azure, an Æsculapian rod in pale between a lancet on the dexter and a poppy slipped and seeded on the sinister, all proper; in second quarter, the Royal Arms of Scotland; and in the third quarter the arms of the City of Glasgow. Above the shield is placed a helmet befitting the degree of the Faculty, above which is the crest, an open book surrounded by an antique burning lamp, and above all the motto, *Conjurat amice*. The supporters are, dexter, Minerva, and sinister, Hygeia, and on a compartment below the shield this motto, *Non vivere sed valere vita*. These arms were adopted in 1863, in substitution for the previous armorial symbol, and were matriculated in 1910, following on the grant of the title "Royal" by the late King Edward VII. At the time of their adoption, careful search of the records of the Faculty failed to throw any light on the date or the circumstances of the adoption of the previous symbol. The old symbol was the rod and serpent in the centre of a shield and flanked by lancet and poppy; and the motto was the *Conjurat amice* of Horace, which might be rendered "in amity to dwell," and might be considered an allusion to the dual composition of the Faculty. No reason is given in the Minute of 1863 for the adoption of the second motto. It is evidently been held to express the chief object of the Faculty—namely, care for the health of the public. The reverse of the medallion is inscribed *Donum Dedit R. M. B. MCMXXV*.

The badge, which is worn suspended round the neck by a dark blue riband, was designed and manufactured by Edwards, Buchanan-street, Glasgow.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1926 statistics of two seaports, three textile, and three cathedral towns :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality from childbirth.
ull .. .. (294,600)	21·6	12·8	1·18	1·37	2·8	1·5	13·5	82	3·3
ortsmouth .. (231,500)	18·2	11·7	0·95	1·38	1·9	1·6	8·0	55	3·1
radford .. (288,700)	16·3	13·6	1·01	1·59	2·1	1·4	15·3	92	7·0
olton .. .. (177,000)	16·3	14·1	0·93	1·33	2·8	1·8	16·2	101	3·4
reston .. .. (124,200)	17·4	12·8	1·13	1·34	2·2	1·7	11·1	90	7·8
orwich .. (123,500)	17·3	10·6	0·91	1·34	—	—	3·7	53	3·7
ork .. .. (84,430)	18·0	12·0	0·86	1·39	1·6	2·2	10·9	65	4·5
ester .. .. (41,913)	19·9	13·0	1·03	1·43	2·6	1·4	11·9	80	2·4

The neonatal mortalities were markedly higher in the mill wns: Bradford 39, Bolton 44, and Preston 42; to be compared ch Hull 30, Portsmouth 23, Norwich 21, York 34, and ester 26.

Hull.

Dr. W. Allen Daley reports that closer coöperation s been secured with the school medical department. n Sept. 1st Dr. James Fraser, the first school medical icer, retired. The medical officer of health has now en appointed school medical officer and all the eventive medical services are under a unified mmand. All the clinics will be made available for ses of every age.

The new municipal V.D. clinic was opened in tober and takes the place of the clinic previously ried on at the Royal Infirmary. The new building thoroughly well equipped as shown by plans and otographs. The men's entrance is in one street d the women's in another. Dr. Edward Harrison, senior clinical officer, and Dr. R. J. Barlee, assistant, both "part-time," conduct all the ekly sessions except one for married women and ldren, which is taken by Dr. Susan Gilchrist, the ternity and child welfare officer. In the early days, s Dr. Daley, it was thought that an ad hoc clinic uld not prove successful, but there is every reason believe that the new Hull centre will be quite as ccessful as ad hoc centres have proved elsewhere. e most serious defect of the scheme has always been failure of patients to make continuous attend- e and the failure is not peculiar to seamen. "No than 160 male cases of syphilis ceased treatment ore completing the first course" out of a total of . When the year opened an outbreak of small-pox in progress, which began in October, 1925, and ases occurred in the first quarter of 1926, the last e being reported on March 16th. On Sept. 30th se of chicken-pox was notified in an unvaccinated , which was visited by the M.O.H. and ultimately nd to be small-pox. One further case in an unvac- ted boy was the only result.

health exhibition held in the city hall, Oct. 16th 23rd, appeared to be productive of much good. s was, of course, in addition to other methods of th education as to which Dr. Daley puts the work he health visitors first, but thinks their importance ld be rivalled by health teaching in the schools if this were done according to a fixed syllabus instead of in the present haphazard way. Dr. Daley pleads for an early decision as to the future of the Poor-law hospitals and that the dual hospital service at present provided by the ratepayers should be unified and put to the best possible use whatever its origin. Much activity is being displayed as regards environmental hygiene. The water-supply of the courts is being improved. Agricultural drains run through the city and a nuisance is caused by the silt removed from them when they are cleansed; some of the more important are therefore being cleansed by the city engineer. It is hoped to secure by legislation standard dust-bins for all premises and not only for dwelling-houses. At present more than half the refuse is taken to tips. The tips are becoming filled up and the best method of disposing of the refuse is under consideration. The privy-conversion scheme is being carried out at a very rapid rate; 7182 conservancy closets were dealt with during the year and there are now only 17,500 to be dealt with.

A record of ultra-violet light is kept on the top of the telephone exchange. Hull receives less of this light than the few places with which it can be compared. Hours of bright sunshine in 1926 were 1299·2, to be compared with 1117·9 in 1925. An effort is being made to reduce domestic smoke on the municipal housing estate by the provision of a "Cookanheat" apparatus. This has already been fixed in 476 houses and will be installed in 1724 more. "All the cooking is done on the same coke-heated stove which supplies an abundant amount of hot water for baths and washing and also heats the whole house by means of a radiator in every room." In the 69,000 houses of the city there are 33,658 gas-cookers and 23,152 gas-fires. A successful course of lectures and demonstrations on smoke prevention for stokers was held at the Technical College with an average attendance of 60. Fish-curing establishments increased from 50 to 56 during the year, and the health committee has decided that in future these places must be fitted with the revolving-hooded type of cowl.

The health committee takes the stand that persons who sell milk in unopened bottles must be registered as purveyors of milk, even although their premises are not legally dairies. Of 28 samples of milk examined five contained tubercle bacilli. Two farms were involved, but in neither case was the offending cow found. Satisfactory arrangements have been made to meet the puerperal fever regulations and antenatal work makes some progress. The births numbered about 6400 and 1153 patients attended the two ante-natal clinics conducted at the maternity centre by Dr. Gilchrist and at the maternity home by Dr. E. M. Townend. The number of cases delivered in the home during the year was 532, 495 by midwives and 37 by doctors.

Portsmouth.

Dr. A. Mearns Fraser says that further steps were taken towards the provision of a new combined maternity hospital and child welfare centre, and that progress has also been made during 1926 in housing. The number of houses completed was 682, more than in any year since the pre-war period, when the annual average was 760. A pair of Atholl steel houses are to be erected as an experiment. At a meeting with representatives of the county council and of the rural district councils of Fareham and Havant, a decision in favour of a planning scheme for the city and the immediately adjoining areas was arrived at.

Dr. A. Campbell, the V.D. medical officer, gives some particulars of the work of the clinic during the last ten years. During the first five years most of the patients were in the acute infectious stage. Now a considerable percentage are persons who contracted venereal disease many years ago. It is claimed that the official treatment of gonorrhœa in females will remove the need for much of the treatment which has hitherto been required in hospitals for women. The patients include young girls, but the number of children infected in Portsmouth is quite small.

Regular and adequate treatment for 185 cases of stricture has been provided. Dr. Campbell refers to syphilis as "a rapidly disappearing disease," and states that "223 cases of neurosyphilis are now living under happier conditions, most of them able to work and exist in comfort, a marked contrast to the outlook for such cases ten years ago." The 547 cases of congenital syphilis are with few exceptions growing up into healthy members of the community. Dr. Campbell concludes that the diminution of syphilis is due in a large measure to free treatment and increased knowledge of prophylaxis, the latter being of much more value in syphilis than in gonorrhœa. Dr. Ruby N. Foggie, the child welfare medical officer, held an antenatal clinic at the maternity hospital which was attended by 724 women. Antenatal work is also carried on at the Royal Naval Maternity Home. An insurance scheme is to be put in operation for the payment of the fees of doctors called in by midwives, on the same lines as that for the county of Hampshire. 118 children suffering from various forms of crippling were sent to the Treloar hospitals, where 55 beds are reserved for Portsmouth.

The hours of bright sunshine recorded during the year were 1688, as compared with an annual average for the previous decade of 1796.

Bradford.

Dr. J. J. Buchanan reports that 1230 privies were converted into water-closets, leaving only 1170 to be dealt with. There are, however, 7440 houses supplied by waste-water closets. During the coal dispute foreign coal with a higher ash and a lower volatile matter content was burnt and caused less smoke, although much inferior in calorific value. Observations show that the deposit of cinder grit is usually greater at night time and that grit is chiefly deposited within 400 yards of a chimney, while fine ash or flue dust may be carried 1000 yards with ordinary wind velocities. The grit emission from chimneys is usually due to the use of low quality fine slack, and Dr. Buchan is thankful that few firms show such callous indifference to the welfare of the surrounding inhabitants as to burn this class of fuel. About half the milk of Bradford is produced within the city by a cow population numbering 3322. Among these the veterinary inspector found 21 tuberculous animals during the year; 14 had tubercle of the udder and seven other forms of tuberculosis; for these 21 animals the owners received £125 19*s.* 6*d.* as compensation, while the salvage was £70 13*s.* 1*d.* Of the 311 samples examined for tubercle 32 gave a positive result and all were from outside milks. Fourteen farms were involved. On six of these no tuberculous udder was found, but on the other eight farms ten cows with tuberculous udders were found and slaughtered.

Bacteriological examination of 1808 samples of shell-fish showed that, "as in previous years," the majority of mussels and cockles are heavily polluted. The water supplied from Barden Moor and Thornton Moor, though better than last year, was still somewhat unsatisfactory, judged by the presence of *B. coli.* The possibility of an avian source for these bacilli is not touched on however. The radiographic work for the tuberculosis dispensary is carried out at St. Luke's Hospital, but it is found that for the control of artificial pneumothorax treatment "screening" is of vital importance, and a high-powered X ray unit is therefore needed for the dispensary. The removal of the V.D. centre to the municipal hospital has not prejudiced its efficiency, and it is thought that the attendances have been improved by the local powers for compulsory notification for cases who fail to persevere with treatment. The existence of these powers has caused patients to resume treatment who have discontinued, and there is no reason to think that it has had the effect of deterring patients from seeking treatment.

The number of new houses erected during the year was 2193, of which 1241 were municipal. This is the highest number of new houses in the records of the city. At the close of the year there were 1161 municipal houses under contract. The Bradford Corporation Act of 1925 gives power for the removal to an institution of persons who are physically incapable of keeping their homes in a sanitary condition. This power was used in two cases during the year, one, a female, aged 70, of intemperate habits and other, a male of 79, physically incapable owing to cerebral hæmorrhage.

Bolton.

Dr. C. W. Paget Moffatt, referring to the increase in the infant mortality-rate from 87 in 1925 to 101 in 1926, says that the main factor in the reduction of infant mortality is the education of the mother, and that there is ample provision in Bolton for assistance to mothers in the care of their infants. He also emphasises what is being done to prevent maternal deaths from childbirth. 2600 out of the 2900 births were attended by midwives and an antenatal clinic is provided to which they may send their cases where any difficulty is anticipated. A trained nurse is available to visit the patient, and the advice of a consultant whenever the medical attendant wishes. There are facilities for laboratory examinations and an excellent maternity home with 18 beds at moderate charges and free hospital treatment when needed.

The scheme for the conversion of privies and pail closets makes good progress; 1562 of the former and 351 of the latter were replaced by water-closets during the year. The local authority makes a grant of £4 for each conversion, and Dr. Moffatt thinks that a similar grant should be available for the replacement of the 15,000 waste-water closets by fresh-water closets. The public abattoirs in Bolton only deal with less than one-sixth of the slaughtering as there are still 19 private slaughter-houses. The travelling vans cause no anxiety; 65 of these passed through in 1926. Their occupants were healthy and took a pride in seeing that their conditions were good. The stationary vans are "a totally different proposition." They number about 70; many are merely large wooden boxes on old lorries and they constitute a distinct danger to health.

About 2620 cows are stalled in the borough, and among these during the year nine cows with tubercle of the udder were found. There were two successful prosecutions under the Tuberculosis Order, one for failure to notify (penalty £5) and the other for failure to isolate a diseased animal (fined 5*s.*). The public analyst (Mr. H. Hurst) states that over 70 per cent. of the milk vended in Bolton comes up to the Grade A standard, and he thinks that the standards for all designated milks might be raised. Since September 1924, insulin has been supplied free to uninsured patients who could not afford to pay for it. The hours of bright sunshine were only 945, 66 hours below the normal.

Preston.

Dr. F. A. Sharpe says the measures for the protection of infant life have been amplified by the inauguration of a central clinic where facilities are provided for the treatment of minor ailments in children and of dental defects in nursing and expectant mothers and young children, and there is a qualified masseuse to deal with cases of rickets and malnutrition. Dr. Sharpe thinks there is much unnecessary poor health among children caused by errors in nutrition, and that the unwearying efforts of the health visitors and the classes in cookery and housewifery organised by the Voluntary Workers' Association are of great value in this respect. The tuberculosis scheme has been strengthened by the opening of the "Chestnuts" Sanatorium in September with 13 beds for males and 17 for women and children. Dr. Sharpe does not anticipate, however, any striking progress until trade and housing are better and there is a marked improvement in atmospheric purity. He laments the apathetic attitude adopted towards smoke pollution.

The picking of mussels from the Ribble estuary was prohibited in October, 1923. The inspector paid several visits to the beds during 1926; it was suspected that

mussels were brought up the river from Lytham, and plain-clothes constables were successful in making one seizure of bags of mussels. Out of 137 samples of milk 2 were found to contain the tubercle bacillus, and in the follow-up 16 farms were visited and 12 cows affected by tubercle of the udder were found and slaughtered. Dr. Sharpe points out that this weeding out of tuberculous udders by milk sampling has only a limited application, and that uniform veterinary inspection of all milking cattle should be the real objective throughout the country.

Norwich.

Dr. V. F. Soothill, who succeeded Dr. Cooper Pattin (on his resignation after 33 years' service) on March 31st, has much to say about the evil conditions of life in the older parts of the city. The overcrowding is explained by a chart, which shows that the decline of house-building began in the first years of the century and that there are nearly 20 years of arrears to be made up. During 1926 776 new houses were completed, of which 544 were municipal and of which 13, erected by other enterprise, received State assistance. At the end of June an outbreak of paratyphoid fever began. There were over 60 cases, mostly in July. Milk and ice-cream both came under suspicion, but the exact cause of the outbreak was not clear. There were no deaths.

York.

Dr. P. R. McNaught says the noteworthy features of the year were the approval of the council to the scheme for the extension of the isolation hospital and the making of arrangements for the treatment of puerperal fever and pyrexia. In the older parts of the city there are many old and dilapidated houses and overcrowding of houses on unsuitable sites. At the end of the year the corporation had completed 711 houses on their Tang Hall estate and 374 more houses were in course of erection. The waiting-list for Tang Hall estate houses is 1700 strong. The overcrowded houses known to the health department number 250 and no effective action can be taken owing to the shortage. It is estimated that 682 houses should be closed; 200 of these are in the Hope-street unhealthy area, the scheme for which has received the sanction of the Ministry. This area covers 3½ acres and houses a population of 805. A nuisance caused by the emission of smoke, gaseous vapours, and grit from the water-gas plant of the York Gas Co. arose in 1925, but up to now no remedy has been provided. A grit nuisance caused by the municipal electricity works has been remedied by additions to the steam-raising plant. The hours of bright sunshine totalled 1244·3, as compared with 1334·3 in 1925.

Chester.

Dr. D. Rennet says that the city's water-supply is taken from the river Dee, within the city boundary, about one and a half miles above the weir. Chester has no control over the many sources of pollution of the Dee. Some years ago an attempt was made by another authority to obtain water from one of the largest and purest tributaries of the Dee. A similar proposal is again under consideration, but Chester has taken no steps either to prevent this or to ensure an adequate and satisfactory supply for itself. The chemical and bacteriological examinations confirm the unsatisfactory nature of the present water-supply. Progress has been made in the matter of housing, but many years will be needed at the present rate to cope with the serious overcrowding. The new houses built in the city during the year numbered 238, and in addition the corporation built 102 outside their boundary. Meat-marking is now well established at the abattoir and the butchers fix up explanatory cards in their shops as to the origin of the mark. It has not been found practicable to extend the marking system to the seven private slaughter-houses scattered about the city. A butcher and pig-dealer were fined £20 and £10 respectively in connexion with the attempt to sell obviously tuberculous pork.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 26TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 233 (last week 226); scarlet fever, 2218; diphtheria, 1500; enteric fever, 144; pneumonia, 1175; puerperal fever, 28; puerperal pyrexia, 100; cerebro-spinal fever, 9; acute poliomyelitis, 10; acute polio-encephalitis, 4; encephalitis lethargica, 28; dysentery, 16; ophthalmia neonatorum, 82. There was no case of cholera, plague, or typhus fever notified during the week.

Of the 144 cases of enteric fever 54 were notified from the county of Hertford (where the milk-borne outbreak of paratyphoid is on the wane); 46 of these were from Hemel Hempstead (U. and R.D.), 5 from Watford (U. and R.D.), and 1 each from Barnet, Great Berkhamsted, and St. Albans.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 39 (9) from measles, 4 (0) from scarlet fever, 6 (0) from whooping-cough, 32 (8) from diphtheria, 50 (10) from diarrhœa and enteritis under two years, and 66 (10) from influenza. The figures in parentheses are those for London itself. The deaths from enteric fever outside London occurred in Reading and Bristol. The number of stillbirths registered during the week was 295 in the great towns, including 49 in London.

Obituary.

MAITLAND THOMPSON, M.R.C.S. ENG.

WE have to record the sudden death of Dr. Maitland Thompson, at the age of 66, at his home in Richmond, Surrey. The son of the late Mr. Thompson, J.P., of Workington, Cumberland, he was educated at Repton and St. Bartholomew's Hospital, and qualified as L.R.C.P. Edin. and M.R.C.S. Eng. in 1884. After holding the posts of house surgeon and house physician at the West London Hospital in 1886 he was attached to the Scots Guards and accompanied Lord Wolseley's expedition for the relief of General Gordon at Khartoum. On his return he worked for a time in Lincolnshire, but later moved to Hemel Hempstead, where he was appointed surgeon to the West Herts Hospital and practised surgery for 25 years. Always interested in local affairs, he was a member of the Hertfordshire County Council and held the office of mayor of Hemel Hempstead, of which borough Astley Cooper, a descendant of the eminent surgeon, had not long before been the first mayor. He took a leading part in politics, was chairman of the local Conservative Association, and was chosen as a candidate for Parliament. At the beginning of the late war he joined the Royal Army Medical Corps and was engaged on home service at different stations until 1919, when he retired to Richmond. In retirement he enjoyed gardening, golf, tennis, and other sports, of which, as of shooting, he was very fond. He was also very active in local church affairs and was a keen Freemason. As a striking example of his genius for friendship it may be mentioned that for 42 years he dined, together with friends made during student days, on May 27th each year.

Dr. Thompson leaves a widow and two sons, his second son having died in 1918.

WALTER CHARLES ORAM, M.D. DUB.

Dr. W. C. Oram, who died on Nov. 28th after a comparatively short illness, was born at Windsor, Nova Scotia, in 1875, and was the son of Mr. John Earle Oram, Professor of Experimental Science at King's College in that province. Educated in Dublin, first at the High School and afterwards at Trinity College, he early showed scientific ability inherited

from his father, and distinguished himself in physics and chemistry. Qualifying in 1900, he spent some time in the study of public health, but a natural bent towards physical investigation soon afterwards led to his taking up radiological work. In 1904 he went to Liverpool as assistant to the late Dr. Stopford Taylor, and took charge of the electrical department of the Skin Hospital in Pembroke-place. It was not long, however, before other and more important appointments came his way, and ultimately he became honorary radiographer to the David Lewis Northern Hospital, the Liverpool Stanley Hospital, St. Paul's Eye Hospital, and the Southport Infirmary. All this involved a great deal of work, to which he devoted himself until a week before his death. During the war Dr. Oram was on the staff of the Western General Hospital, and for a time was attached to the 57th General Hospital of the British Expeditionary Force. Apart from radiology, he was much interested in diseases of the skin. The scientific papers which he wrote were not very numerous, but were remarkable for their lucidity, and showed wide comprehension of the subjects with which he dealt. He was an accomplished and ingenious practitioner, many of the devices which he employed being of his own invention. In person he was courteous and sympathetic, and the profession in Liverpool held him in considerable esteem.

Dr. Oram married a daughter of Mr. J. W. Bright, and she survives him with one daughter.

THE LATE MR. ANGLIN WHITELOCKE.

Prof. Grey Turner writes: I would like to add a few personal notes to your admirable obituary notice of Anglin Whitelocke, whom I first met at the annual meeting of the British Medical Association held in Oxford in 1904. He was the local vice-president of the Surgical Section and as a member of the executive and other committees worked hard to make the meeting the success which all present remember. During that week the Whitelockes kept open house and seemed greatly to enjoy dispensing hospitality. We next met in Paris in 1911 at one of the early meetings of the Provincial Surgical Club, as it then was, and regularly afterwards on visits to continental clinics or to surgical centres at home. On these occasions he proved a most charming and delightful companion, always ready to enliven the long journeys by his conversational powers and to add the results of his wide experience to the general store. He loved to speak of the time when he acted as house surgeon to Sir William Macewen, an experience of which he was ever proud, and his "chief" of those days remained his hero to the end. The spring meeting of the club, in 1914, was held in Oxford, and Whitelocke on that occasion carried out a whole series of operations, and I especially remember his rapidity, quickness of decision, long incisions, and the way he unhesitatingly explored the knee-joint with the finger. There were also demonstrations of cases at the hospital, but he saw to it that the strictly scientific side was not neglected, and in the afternoon after the whole club had been entertained to tea at his house, he arranged with a colleague—it was Dr. Gunn—to give us apt laboratory demonstrations on the action of drugs on living muscle. Osler and Whitelocke were firm friends and the Regius professor of medicine gave us a delightful talk at the Bodleian on the history of surgery as illustrated by the books in that famous collection. None present is likely to have forgotten the evening when we dined together in Hall at Lincoln, of which college Whitelocke was an honorary graduate. The master, Dr. Merry, presided over the happiest of gatherings, and on looking back it is sad to realise how many of those present have since joined the majority.

After the war our peripatetic surgical society renewed its wanderings, and no one was more welcome than Whitelocke, who was as charming as ever, but it was noted that he lacked something of the old buoyancy. In the spring of 1927 ill-health prevented him from joining the tour of the club to Spain. This was a bitter disappointment to him and to us all but he came to Victoria station to see us off and wish us a good journey. Those of us who saw him then cannot feel surprised that it was for the last time Whitelocke can ill be spared and will be greatly missed by hosts of friends.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. C. A. G. Phipps is placed on the Retd. List with the rank of Surg. Capt.

Surg. Lt.-Comdrs. L. W. Gemmell and R. P. Ninnis to be Surg. Comdrs.

Surg. Lieut. (D) T. E. Brevetor to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. J. E. Purves to be Surg. Lt.-Comdr.

Proby. Surg. Sub-Lts. J. O. Clyde and H. S. Waters to be Surg. Sub-Lts.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt. Col. W. Riach retires on retd. pay on account of ill-health, and is granted the rank of Col.

Maj. H. C. Winckworth to be Lt.-Col.

ARMY DENTAL CORPS.

Lt. R. A. Roth to be Capt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. A. E. Weld, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Maj. W. E. C. Lunn-Barker, R.A.M.C., Reg. Army Res. Off., relinquishes appt. under Art. 507 (*b*), Royal Warrant for Pay and Promotion, 1926, and resumes the rank of Lt.-Col.

TERRITORIAL ARMY.

J. D. Robertson to be Lt.

ROYAL AIR FORCE.

The undermentioned are granted short service commissions in the rank of Flying Officer for three years on the Active List: V. V. Brown, M. Clancy, W. Heron, F. L. Lipscomb, J. F. McGovern, C. P. O'Toole, S. B. S. Smith, G. H. J. Williams, and D. A. Wilson.

The undermentioned are promoted to the rank of Flight Lt.: E. Thompson and E. A. Aslett.

Flight Lt. J. E. Cox relinquishes his temporary commission.

RESERVE OF AIR FORCE OFFICERS.

Flying Officer C. J. MacQuillan is transferred from Class D II. to Class D I.

INDIAN MEDICAL SERVICE.

Capts. G. B. Hanna, Pestonji Rustomji Vakil, and F. M. Kirwan to be Majs.

Lt.-Col. L. T. R. Hutchinson retires.

Lt.-Col. W. M. Anderson, Agency Surg., to be Resident Surg., Hyderabad. Dr. B. G. Kane, Asst. to Civil Surg. Raipur, has been appointed to officiate as Civil Surg. Raipur. Maj. L. H. Khan has been appointed Superintendent, Central Jail, Nagpur. Maj. N. S. Jatar, Superintendent, Central Jail, Nagpur, has been appointed Superintendent, Central Jail, Jabbulpore. Capt. G. W. Cearns Asst. Civil Surg., Allahabad, has been appointed R.M.O. European Civil Hospital, Allahabad. Lt.-Col. F. A. Barker has been appointed Insp. Gen. of Prisons, Punjab. Lt.-Col. J. Frizelie has reverted to military service. Lt.-Col. J. Morison has been appointed Director, Pasteur Institute, Shillong. Maj. H. C. Godding to officiate as Officer Commanding British Military Hospital, Peshawar. Maj. N. D. Puri to officiate as Insp. Gen. of Prisons, Punjab. Capt. A. C. Chatterjee officiating Civil Surg., Serampore, has been appointed to act as Civil Surg. of Burdwan. Lt.-Col. Godson, Civil Surg. Hooghly, has been appointed Civil Surg., Serampore. Lt.-Col. W. D. Speedy has been appointed to the Medical Charge Civil Station, Barrackore. Majs. J. A. Sinton and G. Covell have been appointed Director and Assistant Director respectively of the Central Malarial Organisation. Lt.-Col. H. Thoburn has been appointed Surgeon on the Viceroy's Personal Staff. Maj. St. J. E. Henricks, officiating Civil Surg. Mandla, has been appointed to the executive and Medical Charge, Subsidiary Jail, Mandla. Maj. S. L. Mitra has been appointed to act as Director of Public Health, Patna.

DEATHS IN THE SERVICES.

Inspector-General Hadlow, R.N. (retd.), who died on Nov. 30th at Southsea, aged 91, qualified with the L.S.A. in 1857, and obtained the M.R.C.S. Eng. two years later. He was assistant surgeon on the *Conqueror*, and was present at the attack of the batteries in the Straits of Shimonoseki, Japan, in 1864. He received the Gilbert Blane medal and retired in 1894.

PATHOLOGY AT THE LONDON HOSPITAL.

FACILITIES FOR RESEARCH.

AT the opening of the Bernhard Baron Institute of Pathology at the London Hospital on Tuesday Lord CHUTSFORD said that the work of the medical college could not be separated from that of the hospital. It was a narrow view of things that limited the work of the hospital to the cure of the patient only; we must care for the future sick, learn by experience, and search for remedies against diseases at present incurable.

Sir HUMPHRY ROLLESTON pointed out that the great services unobtrusively rendered by a pathological institute were to help the patients by routine examinations, to advance knowledge so as to prevent disease, and to educate the future medical men of the country. From the purest charitable motives the public often earmarked donations and subscriptions for the use of hospital and patients only, thus excluding pathological or other departments whose work was essential to efficient treatment. It should be realised that the departments of pathology, bacteriology, and clinical pathology and biochemistry were just as essential to a modern hospital as were the radiological department, the operating theatres, and the wards; it was, in fact, rather strange that radiology, which was much younger in years than pathology and considerably the junior of bacteriology, was in general regarded as much more closely related to ordinary clinical practice than its seniors, probably merely because of the position of its work-room—namely, among the out-patient departments. Routine work was not only compatible with, but in an ideal institute was inseparable from research. It was a serious mistake to regard the routine work of a laboratory in the same light as a penny-in-the-slot machine, for though in some cases it may be easy to give a correct opinion, in others it might be very difficult. Not only did the material as collected provide the data for research and analytical conclusion, but out of it there was always something new forthcoming. The importance of enabling research and publication of new information to be made must not be lost sight of in the consideration of the laboratory staff. In addition to the Director, Prof. H. M. Turnbull, there were two assistant directors, Dr. W. W. Woods and Dr. A. B. Hutton, three qualified men as pathological assistants with an honorarium and voluntary assistants. The personnel of a laboratory was even more important than its spaciousness and material equipment, and the London Hospital was extraordinarily fortunate in having the man first, so that he could direct the plans and arrange the splendid new laboratory so generously provided by Mr. Bernhard Baron. The amount of work that had issued from Prof. Turnbull's department during his tenure of office was surprising. Much of his work had been published, but not under his name, for, like the ideal head of a department, he was anxious that his colleagues and pupils should have every facility and encouragement to make use of his store of accumulated material. How many researches he kept secret from the public eye as a result of a severely auto-critical attitude was unknown, and probably only those working in close collaboration with him and cognisant of his teaching had any approach to an accurate knowledge of his unpublished work.

Sir Humphry Rolleston concluded by referring to the great traditions of the London Hospital and to the torch of pathological learning handed on from H. G. Sutton and F. Charlewood Turner and still burning brightly.

THE BERNHARD BARON INSTITUTE OF PATHOLOGY.

Prof. H. M. TURNBULL, in proposing a vote of thanks to Sir Humphry Rolleston, expressed his great pleasure that the Regius Professor of Physic at Cambridge should have opened the Institute. The Chairman of the hospital and the House Committee had done everything in their power to help him in organising the department, but in his early days there had been a great lack of material for pathological investigation. A pathological department should be so endowed that it could continue its work independently of the fluctuation of annual subscriptions, and with a further endowment of £100,000 he believed this object could be attained at the London Hospital.

Dr. ROBERT HUTCHISON seconded the vote of thanks and Mr. Bernhard Baron expressed the hope that he would live to see the Institute bear fruit. The proceedings then terminated.

The Institute, which is an expansion of the Andrew Clark Institute of Pathology opened by Sir Henry Roscoe and Lord Lister in 1907, has been named after Mr. Bernhard Baron in recognition of a gift of £10,000 for building and of £25,000 for permanent endowment. This endowment is supplemented by a sum of £5000 from the Rockefeller Foundation. The following is a description of the laboratories:—

The ground floor is occupied by freezing chambers for the storage of bodies, a mortuary chapel, and a waiting-room for friends; the latter two rooms have a separate entrance from outside. The post-mortem theatre is a separate building on this floor; the sides and roof are of glass and the roof is fitted with ventilators which draw up and burn the vitiated air. The first floor contains 12 rooms; a large room for the investigation of tissues removed at operations, rooms for the director, assistant directors, pathological

assistants, and technicians, research rooms, a room for the clerk and the records, and a room for washing glass-ware. In one of the larger of these rooms the cabinets containing microscopic slides will be stored. On the second floor is a large lecture and class-room to accommodate 50 students. Behind this is a room for storing specimens reserved for lectures, demonstrations or further examination, and a curator's room in which such specimens can be prepared. Two rooms which lie immediately beneath the animal houses have been specially fitted for animal experiment, but can also be used for other research. In another room students can work in their spare time. This floor also has a room for washing glass-ware. On the third floor are placed three animal houses and a fodder room.

The lecture and class-room is fitted for practical work. It has on three sides large windows with lights that swing on pivots so that they may easily be cleaned, and a "factory roof" with north lights; all the lights are fitted with blinds so that the room may be completely darkened when an epidiascope is used. The room for reserved specimens is fitted with iron racks to carry tanks, whilst the whole of the space beneath small windows in one long wall is occupied by a cupboard for small jars and by shelves for larger vessels. This room has a skylight and a tiled floor. The clerk's room will be fitted with a large fire-proof cupboard for the records and cupboards for storing the indices and copies of reports.

The animal houses have asphalt floors provided with gullies, and the cages are carried on cantilever slides. All the other rooms are furnished with benches, fitted with drawers, for practical work, slate slabs for paraffin ovens and incubators, gas points, electric points for lighting and for power, sinks, cupboards, and, usually, wash-hand basins. All the rooms except the animal houses and the room for reserved specimens have rubber flooring. The building is warmed by hot-water radiators, and those in the animal houses are arranged to give specially required temperatures.

Mr. J. G. Oatley, F.R.I.B.A., is the architect.

REMOVAL OF BETHLEM HOSPITAL.—Formal notice has now been given that application will be made to the next session of Parliament for an Act empowering the governors to sell, lease, or otherwise dispose of portions of the Monks Orchard Estate which has been acquired for the erection of the new Bethlem Hospital. The notice is published in the *London Gazette* as from "the Mayor and Commonalty and Citizens of the City of London, Masters, Guardians and Governors of the House and Hospital called Bethlem situate without and near to Bishopsgate of the City of London"—that having been the site of the original hospital.

VITAL STATISTICS OF THE IRISH FREE STATE.—The annual report for 1926 of the Registrar-General of the Irish Free State was issued recently. The total number of births registered was 61,176, being 893 less than in 1925; and the total number of deaths was 41,740, being 1910 less than in 1925. Tuberculosis caused 4362 deaths, the lowest ever recorded in the Free State, while the deaths from cancer (3021) show an increase of 118 over the highest annual number ever previously recorded—viz., 2903 in 1924. Of the 61,176 births registered, 59,460 (97·2 per cent.) were legitimate, and 1716 (2·8 per cent.) illegitimate. The mortality from all causes in 1926 was 0·57 per 1000 below that for 1925, and 1·58 per 1000 below the average for the ten years, 1916–25. In urban areas the mortality was 15·52 per 1000 and in rural districts 13·44 per 1000. Infant mortality in 1926 was 74 per 1000 births, which was 6 per 1000 above the rate for 1925—viz., 68 per 1000. The rate for rural areas was 56 per 1000, and for urban areas 110 per 1000 births. The deaths from measles number 519, 321 above the number recorded in 1925, and 267 above the average for the ten years, 1916–25. Of the 41,740 deaths at all ages, 6781, or 16·2 per cent., were deaths of children under 5 years, including 3676 deaths of males, or 17·6 per cent., of the male mortality at all ages, and 3105 deaths of females, or 14·9 per cent. of the total deaths of females. Deaths of persons aged 95 years or upwards numbered 287, and they include 49 whose ages at death were returned as 100 years or upwards. Of the 41,740 deaths, 14,343, or 34·8 per cent., of the total deaths were 70 years of age or over. Deaths caused by violence in 1926 numbered 889 (0·30 per 1000), 73 more than recorded for 1925. Of the 889 deaths, 87 were classed as suicide, 44 to homicide, one to execution, leaving 747 to other deaths by violence, the majority of which were definitely stated to have been accidental. The number of emigrants from the Free State to "places outside of Europe and not within the Mediterranean Sea" during 1926 was 30,359 (as compared with 30,302 in 1925), and the number of immigrants was 1983, resulting in a net migration of 28,376 persons from the Free State in 1926.

"Audi alteram partem."

CATARACT EXTRACTION WITH PERIPHERAL IRIDECTOMY.

To the Editor of THE LANCET.

SIR,—Of the operation described by Dr. J. T Tennent in your issue of Dec. 3rd, I have had many years' experience. It is the one which, in my opinion gives the best results. That some of my colleagues at Moorfields share this opinion is shown by the fact that this particular operation was performed 84 times at that hospital during the seven years 1919–25 inclusive. While in complete accordance with Dr. Tennent's statement that *the* most important advantage of peripheral over complete iridectomy is that the former prevents inclusion of lens capsule in the wound, I do not agree with him as to the contra-indications. No intraocular operation of any kind should be undertaken unless all risk of infection from conjunctival or lacrymal sac infection has been removed, while excess of cortical matter can in most cases be got rid of by washing out the anterior chamber. Again, loss of vitreous after removal of the lens, in consequence of the performance of a peripheral iridectomy, is an accident which I have never known to occur.

The conditions in which a complete iridectomy is preferable to a peripheral are, in my opinion, three in number—viz.: (1) the presence of posterior synechiæ; (2) when the pupil is so rigid that expression of the nucleus through the intact sphincter cannot be done without the employment of undue force; and (3) when the iris, after having been replaced, will not remain in position; this is usually caused by a tendency to bulge on the part of the vitreous. The accidental inclusion in the wound of a small mass of uveal pigment from the posterior surface of the iris has, in my experience, never caused the slightest trouble, provided that the iris itself has remained entirely free.

There are, of course, many practical points of importance in the technique of the operation.

I am, Sir, yours faithfully,

R. AFFLECK GREEVES.

Wimpole-street, W., Dec. 6th, 1927.

THE NUTRITIVE VALUE OF BREAD.

To the Editor of THE LANCET.

SIR,—The contribution to our knowledge of the all-important subject made by Dr. Cramer and Dr. Mottram is extremely valuable. It will, however, fail in its purpose if attention is to be centred on any proprietary article rather than on the all-round improvement in the quality of bread as ordinarily supplied. "Hovis" is undoubtedly very superior in nutritive quality to white bread made from "patent" flours. But it is, after all, a case of "robbing Peter to pay Paul." The germ which enriches "Hovis" to an unnecessary extent could be made better use of if it was distributed throughout the nation's bread. There is not enough bread to go round if all bread was made to contain 25 per cent. of germ—nor is it necessary that it should. During the milling process various "streams" of products are obtained containing varying proportions of the different parts of the grain. It is only necessary to combine these various products in order to build up a flour which will contain a due proportion of all the constituents of the grain. Such combinations could be made to suit all tastes and requirements, and yet be infinitely superior to the "patents" now so generally used despite their poverty in vitamins and mineral salts. These reconstituted flours might be almost white in colour and be perfectly adaptable to ordinary methods of baking.

This would appear to be the solution of many,

ot all, of the difficulties which stand at the present
the way of the general bread reform.

I am, Sir, yours faithfully,
S. HENNING BELFRAGE.

Gloucester-place, W., Dec. 5th, 1927.

To the Editor of THE LANCET.

SIR,—The letters of Prof. V. H. Mottram and
iss G. Hartwell in THE LANCET of Nov. 26th may be
nswered together. In our recent paper we said that
rof. Mottram had made public the erroneous state-
ent that white bread contains an abundant supply
vitamin B, and is not greatly inferior in this respect
wholemeal bread or germ bread. Prof. Mottram
nies having said this, and hopes that our scientific
curacy is greater than our controversial. We there-
re quote the manifesto signed by him, Miss Hart-
ell, and others which appeared in THE LANCET of
ly 23rd, 1927 :—

"While we admit that vitamin B, which is essential to
alth, is present in wholemeal flour and practically absent
om white flour, we do not subscribe to the statement that
is not contained in white bread and that the use of white
ead denies the human system the necessary amount of
is vitamin."

"The fact is that any lack of vitamin B in white flour is
finitely remedied when the flour is made into bread by
e addition of yeast, which contains plenty of it."

We also said that the experiments of Miss Hartwell
which Prof. Mottram's statements appear to be
sed were faulty because the vitamin-B content of
r diet was due to the butter which she included in
r diet, and not to the white bread, and because
proper control experiments were carried out
nich would have demonstrated this fallacy. Miss
artwell states in her letter that controls were made
d that we overlooked that part of her paper. We
d not overlook any part of her paper. If the reader
ll refer to her paper he will find that the butter
ed by her was not tested for the absence of vitamin
which Miss Hartwell merely presumes. The
ader will find, moreover, that rats fed on this butter
d white bread made with baking powder instead
yeast increased in weight progressively during
weeks from 40 to 100 grammes. This diet must
erefore have contained considerable amounts of
amin B. Since this vitamin is absent from white
ur—as the manifesto correctly states—and from
king powder, the source of vitamin B in this experi-
nt must have been the butter. This fallacy
iates all her results. With proper control experi-
nts it can be shown conclusively that rats cannot
e on a diet in which white bread is the only source
vitamin B.—We are, Sir, yours faithfully,

W. CRAMER,
J. C. MOTTRAM.

mperial Cancer Research Fund, Radium Institute,

CRIMINAL LAW AND INSANITY.

To the Editor of THE LANCET.

SIR,—A consideration of Lord Hewart's David
oyd Roberts lecture leads me to ask for space to
cline the following points. I assume that the two
igatory conditions of the McNaghten judgment
ve been fulfilled. The third condition laid down
this judgment is an alternative one—namely, that
a defect of reason brought about by a disease of
mind must prevent the accused from knowing
nature and quality of his act, or prevent him from
owing that what he was doing was wrong.

Taking the first alternative I further assume that
accused knows the *nature* of his act—e.g., the
ughter of a human being other than himself.
hat meaning does the word *quality* bear? Can a
son be said to know the quality of his act if he is
ware of its probable consequences to himself?
not, what is the minimum length of time for which
s unawareness must exist to constitute legal
anity; does the law insist that such ignorance
st exist before, during, and after the commission
of the act, and, if so, for how long? If it does not so insist or fail to fix the duration, it appears to me that to be unaware of the quality of an act in the sense of a failure to realise the consequences to himself for a period only covered by the time necessary to commit the act brings an uncontrollable impulse within the bounds of the McNaghten judgment. For the words are "nature *and* quality," not "*or* quality."

Taking the second alternative, is the word *wrong* to be construed as illegal or wrong according to the ethical and/or moral standards or standard of the insane person? Such a person may commit an act which he regards as righteous while at the same time taking precautions to avoid the legal consequences of discovery. It may be that these points have been already dealt with; if not, I think they may help to clear up the differences between the medical and legal view of insanity.

It is perhaps not generally known outside the medical profession that many insane minds reason in a manner even more appallingly logical than that of an eminent lawyer. Their acts, however horrible, are the reasoned consequences of mistaken ideas. Lord Hewart says that the fact that a man thinks he is John the Baptist does not entitle that man to shoot his mother. If a man who thought himself John the Baptist did shoot his mother I think it would be found that he did so because he was firmly convinced she was Salome.

I am, Sir, yours faithfully,
GORDON WILSON, M.B.

Thurlstone, near Sheffield, Dec. 4th, 1927.

ORGANIC HYPNOTICS.

To the Editor of THE LANCET.

SIR,—I am very glad that Sir William Willcox has again warned medical practitioners against the careless use of barbituric acid derivatives. They are extremely helpful preparations in the treatment of patients suffering from the sleeplessness, irritability, and mental unrest so commonly associated with the psychoneuroses and allied conditions, but extensive experience of their effects confirms my belief that the administration of medinal, veronal, dial, and the rest should be much more closely controlled than I find to be customary.

A patient who took sufficient barbitone to make him sleep for 72 hours told me he had never any difficulty in obtaining as much as he wanted on an old prescription; this large dose was said to be an accident, but as not long after he was decapitated on a railway line I have found it difficult to accept that view. Again, within the last few months dial was suggested as a simple and reliable hypnotic by a doctor visiting a patient of mine in a non-professional capacity. Of course he could not know that this patient had myocardial weakness and attacks of alcoholic nephritis, nor that in the same house was a mentally unstable individual always on the look out for new drugs. However, within a few days the latter so successfully doped himself with dial that urgent stimulant treatment was required to bring him round from a state of profound coma which for a time seemed likely to be fatal.

Drugs that are prescribed without restriction and easily purchased are not regarded by patients as "dangerous"; unless a prescription is written with carefully detailed directions and marked "not to be repeated" they often see no reason why they should not use barbitone-compound tablets as readily and safely as they use aspirin or soda-mint tablets. After all, it is a tablet age, and every household has its favourite cachets and tablets for ready use; but in my opinion it is time we seriously regarded Sir William Willcox's warning and made a rule never to give "open" prescriptions for barbituric acid hypnotics, nor to put patients in possession of more than three or four tablets at a time.

I am, Sir, yours faithfully,
E. L. HOPEWELL-ASH, M.D.

Grosvenor-street, W., Dec. 5th, 1927.

THE WEIGHT OF THE BRAIN OF ANATOLE FRANCE.

To the Editor of THE LANCET.

SIR,—For a century past great importance has been attached to the brains of eminent men, the weight of which is presumed to be above the average—i.e., above 1360 g. or 49 oz. for men (and 44 oz. for women). The most recent weight taken is that of Anatole France, the celebrated French author, by Dr. Guillaume Louis and Dr. Dubreuil Chambardel, who read a paper on the subject at the Academy of Medicine in Paris on Nov. 8th last year. They reported that they found that the weight of the brain of Anatole France was 1017 g. only—i.e., 343 g. less than that of an average male citizen and less than the weight of the brain of an ordinary woman.

The small weight of the brain may, of course, be due to the age of Anatole France, who died three years ago, when he was 80½ years old. But Dr. Louis and Dr. Chambardel held that it was probably due to the nature of the fluid used for embalming the body, for they had performed an experimental test, which revealed that brains soaked in this fluid lost 10 g. in a day. They drew attention to the fact that Gambetta's brain, hitherto regarded as the lightest on record, was similarly prepared by Duval, and weighed 12 hours after embalming 1160 g. and a few hours later 1090 g., but must actually have weighed 1246 g.

Now it appears to me, quite apart from this report, that anatomists still do not know what to look for. That the intellect can have little, if any, reference to brain weight was argued already by Gratiolet, who was no mean authority on this subject. How unreliable—without the fullest details—these brain weights are, is shown by the careful weight taken of the brain of Helmholtz, distinguished for his wonderful researches in optics (*Zeitschrift für Psychiatrie*, 1899). The weight of his brain, including the blood coagulum, was 1700 g. This being removed, the brain weighed 1540 g., but so much blood remained that it was estimated that 100–120 g. should be deducted. This would reduce the brain weight to 1420–1440 g. Helmholtz had therefore a brain not much above the average weight; but how do we know that in the cases of the very heavy brain weights recorded, as those of Cuvier and Byron, allowance was made for the quantity of blood, as was made in the case of Helmholtz.

Lord Byron died in Greece in 1824, and English papers reported his brain weight as six medicinal pounds, a round figure which renders it suspect of being inaccurate. In any case it was probably a Neapolitan or Venetian weight, the former 1924 g., the latter 1807 g., and it was stated that Byron's brain was in a hyperæmic condition, so that probably no allowance was made for the blood which the brain contained. The brain of Cuvier, the famous naturalist and anatomist, remained for a long time the heaviest brain recorded of distinguished men. The weight was stated by Wagner as 1861 g., but this Broca corrected to 1829·96 g. Even thus reduced it exceeds the limits of the normal human brain by nearly one-third. To Spitzka, an eminent American neurologist, the explanation of Cuvier's heavy brain was very simple; it represented not intellect, but healed-up hydrocephalus.

Sir Walter Scott's portraits show an astoundingly large head, especially in height. It is on record that the cranial arch from ear to ear, measured from the mastoid process, was 19 in., whereas the average is only 14·6. The circumference of his head was 23·1 in., the longitudinal diameter 9 in., and the parietal 6·4 in. Yet in the report of the post-mortem examination of Scott the physicians stated that "the brain was not large." The peculiar shape of his skull was attributed to his lameness dating from infancy—another healed-up hydrocephalus. But if, as his physicians supposed, "the sagittal suture closed prematurely," his skull could never have grown to the enormous height we see in his portraits and busts.

Quality of the brain, number, and depth of the convolutions do not account for the differences in brain weights, for we are dealing exclusively with men who have achieved eminence. Nor can they be du wholly to differences in the bulk of the body, for, a Sir William Turner has pointed out: "The huma brain, in all probability, attains its full size and weigh at or about the age of 30, whilst the body not onl increases in weight after this period, but in one an the same individual may vary considerably in weigh at different stages of adult life, without any corre sponding fluctuations taking place in the weight the brain."

Size and weight of the brain can only indicat mental power, but does not tell us whether tha power lies in extent of intellect, in strength of mor feeling, or in power of passion or affection. Th evidence of comparative anatomy must not be ove looked, that we have some parts of the brain common with animals, to administer to our anim wants, and that only those parts which are characte istically human can have any relation to the high intellectual processes and moral qualities for whic man is distinguished—namely, the frontal lobes. is their size and complexity which must be estimate in judging of the superiority of a particular brai This is the view of many distinguished authorities Sherrington, Bolton, Ferrier, Bianchi, and others—b has not yet been sufficiently realised.

We have learned a great deal during the progre of the last 50 years of the brain as an organ of sensatio and motion. What is needed now is research int the mental functions of the brain, to account for th numerous specific intellectual and other abilities man. Brodmann and Elliot Smith have discover about 27 structurally differentiated areas in th cerebral cortex, but we are still ignorant of the functions. If mental manifestation is dependent brain structure and activity, it is time we learn something more about it than we know at present.

I am, Sir, yours faithfully,

BERNARD HOLLANDER.

Wimpole-street, W., Nov. 29th, 1927.

SURVIVAL AFTER OPERATION FOR BREAST CANCER.

To the Editor of THE LANCET.

SIR,—Your report last week of the discussion the Medical Society of London on Nov. 28th on series of cases of long survival after the operatio for breast cancer, contains one important, if obviou error. I am made to say that the method of routi use of radium at the time of the primary operatio which I have practised for the last seven years, h improved my private results by 90 per cent. Wh I actually said was that it had diminished my pe centage of recurrences by 9 per cent., an importa but not a sensational gain. At Montreal last year gave fuller details of my results in a paper read befo the American College of Surgeons. This paper w appear in an early number of *Surgery, Gynecology a Obstetrics*.—I am, Sir, yours faithfully,

W. SAMPSON HANDLEY.

Harley-street, W., Dec. 6th, 1927.

To the Editor of THE LANCET.

SIR,—In your report of the discussion on late resul of operation for carcinoma of the breast at the Medic Society of London, Mr. A. J. Walton is said to ha suggested that "those who spoke hopefully of the cases would be more pessimistic if they had a go follow-up agency at work." Of course, caref surgeons in discussing their results have always tak account of the factor of uncertainty introduced the existence in their records of cases untraced, a actually there are published series where the propo tion untraced was small. In the Leeds data discuss in Report No. 34 of the Ministry of Health's Ser less than 5 per cent. of the 357 patients were untrace The optimistic conclusion reached by Dr. Lar Claypon depends in no way upon neglect of elementary precaution and the results she reach are, within the necessarily wide limits set by ordina

rors of sampling, indisputable. We can take it as certained that of the Class 1 cases (the disease rtainly malignant but entirely confined to the east) almost certainly more than 50 per cent. of e patients and probably more than 60 per cent. ll be alive ten years after operation. We may so take it that of patients operated upon in an average" condition the percentage of survivors ay be as small as 15 per cent., and is not likely to ceed greatly 24 per cent. (a result in reasonable reement with the 13 per cent. reported in the scussion by Mr. Jocelyn Swan, which may perhaps too pessimistic if, in his series, there were any nsible proportion of untraced patients).

Mr. Zachary Cope "raised the question of how many ses would have survived without operation." This estion has been raised before by several investitors and a summary of their results is contained in eport No. 33 of the Ministry of Health's Series. he answer to Mr. Cope's question is that on the erage not more than 12 per cent. of untreated tients are likely to survive so long as *six* years m the date of first recorded symptoms (of course, date anterior to that of possible operation), and most half will be dead within two years.

For reasons set out at length in the report entioned above, I believe that the word "cure," ing ambiguous and hard to define, should not be ed and that we should try to think in terms of ars of life saved. If we do so, I am sure we shall t only agree with the optimistic surgeons but shall d it very hard to escape the conclusion that those o are pessimistic have not discovered some fallacy dden from their colleagues but are merely familiar with the literature of the subject.

I am, Sir, yours faithfully,

Dec. 6th, 1927. MAJOR GREENWOOD.

MERCUROCHROME INTRAVENOUSLY.

To the Editor of THE LANCET.

SIR,—Anyone who has studied the literature on is matter will have been struck with the variation dose and dilutions employed. A word of caution desirable, particularly to those relatively inexpericed in the administration of this organic mercurial. A pharmacologist, to whom I forwarded supplies experiments on animals, sent me the astonishing port that a certain proportion of deaths might llow the injection of 8–15 c.cm. of a 1 per cent. lution (i.e., 0·08 to 0·15 g.) in man. On pointing t to him that a dosage of this kind has been used nically in many cases he modified his opinion to e extent of admitting that there is an enormous riation in the tolerated dose of any drug in animals. imal experiments are of great help, but clinical perience is clearly more valuable. I see the new d non-official remedies says that 10 mg. per kilo variably kills rabbits, yet the dose of 5 mg. per kilo e., 0·3 g. for a 10-stone man) is mentioned in that ork. I have information of the repeated clinical e of 0·1 increasing to 0·2 g. of the compound in this untry, injections in some instances having been ven every day, without any untoward result except mild stomatitis. And, on the other hand, I have formation that 0·1 g., both in 1 and 0·5 per cent. lution, was not tolerated, intense diarrhœa being used.

My own view is that the recommendation of L. S. idgeon (THE LANCET, 1926, i., 172) of 10 c.cm. of 1 in 200 solution as the maximum that should be ven, is a safe one to go upon, reserving bolder sage—e.g., that of Andrew Balfour (*Brit. Med. Jour.*, 25, ii., 1081) (20 c.cm. of a 1 per cent. solution), for ch grave infections as plague.

It would be a great help if those who have had ther experience with mercurochrome intravenously uld communicate it, in order that the dosage and gree of dilution may be determined.

I am, Sir, yours faithfully,

W. H. MARTINDALE.

New Cavendish-street, W., Dec. 6th, 1927.

Medical News.

UNIVERSITY OF DUBLIN: SCHOOL OF PHYSIC, TRINITY COLLEGE.—At the recent examinations the following candidates were successful:—

MASTER IN SURGERY.

Bernard Gluck.

FINAL MEDICAL EXAMINATION.

Part II., Medicine.—A. R. Ewart, J. E. Wells, Kenneth Watson, E. M. Gamble, J. R. Hanna, G. H. Henry, J. H. Stephens, L. R. Brumberg, Wilfreda D. C. T. Piggott, H. S. North, and Christina M'Donald.

Surgery.—*R. R. Woods, J. K. Harper, George M'Donald, G. M. Smith, Ethel M. Weir, J. H. Stephens, G. H. Henry, A. R. Ewart, Isidore Isaacson, R. M. Moore, C. E. G. Nunns, Izaak le Roux, and C. P. Wallace.

Midwifery.—*A. A. Morgan, *H. R. F. Tweedy, R. I. G. Reid, Marie M. E. Lea-Wilson, H. J. Robinson, J. K. Harper, H. E. Knott, F. G. Stewart, C. R. Harris, Julius Horwich, R. F. W. K. Allen, William Crawford, G. W. F. Pratt, D. F. Walsh, A. C. G. Ffolliott, F. O. W. A. Mahon-Daly, Julius Sayers, H. S. Smithwick, Nora A. Stack, E. S. Adderley, J. E. Wells, E. C. Hicks, and G. Q. Chance.

* Passed on high marks.

FINAL DENTAL EXAMINATION.

R. W. Mather and G. M. Titterington.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

Ann Macleod.

UNIVERSITY OF CAMBRIDGE.—By the death of the widow of the Rev. John Henry Ellis, who died in 1912, the University has become entitled to a bequest of approximately £65,000, which can be used for general purposes.

UNIVERSITY OF LIVERPOOL.—The late Emeritus Professor W. Thelwall Thomas has left £5000 to the University of Liverpool to endow a Fellowship in Surgical Pathology.

UNIVERSITY OF DURHAM.—The Chancellor of the University of Durham, the Earl of Durham, has appointed Sir Thomas Oliver, M.D., F.R.C.P., President of the College of Medicine, Newcastle-on-Tyne, to be Vice-Chancellor of the University.

UNIVERSITY OF EGYPT.—Mr. P. C. Raiment, M.R.C.S. Eng., has been appointed to the chair of physiology in the State University of Egypt at Cairo. Dr. Raiment, who took first-class honours in the natural science schools at Oxford, has been for the last six years university demonstrator in biochemistry at Oxford. He will leave at the end of this year.

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES.—A meeting will be held at the Royal Society of Arts, 18, John-street, Adelphi, London, W.C. 2, on Tuesday, Dec. 13th, at 8.15 P.M., when Prof. T. P. Nunn will lecture on Anthropomorphism in Science.

CONFERENCE ON ACTINOTHERAPY.—An international exhibition and conference organised by the *British Journal of Actinotherapy* will be held at the Central Hall, Westminster, from Tuesday, Dec. 13th, to the following Friday. Particulars may be found in THE LANCET, Dec. 3rd (p. 1196), and invitation tickets can be obtained from the office of the journal at 17, Featherstone-buildings, London, W.C. 1.

HOSPITAL ADMINISTRATION.—A three months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Eastern Hospital, St. Ann's-road, London, N. 15, by Dr. F. H. Thomson, the medical superintendent, on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning on Wednesday, Jan. 4th, 1928. Particulars may be had from the clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C. 4.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Dec. 12th, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., Mr. Ernest Clarke will give a lecture entitled Practical Hints in the Correction of Errors of Accommodation and Refraction of the Eye. This lecture is free to members of the medical profession. In January courses will be held in medicine, surgery, and the specialties at the Prince of Wales's General Hospital; in cardiology at the National Hospital for Diseases of the Heart (limited to 20); in diseases of children at the Children's Clinic; and in psychological medicine at the Bethlem Royal Hospital. Information, syllabuses of special and general courses, and tickets may be had from the Secretary of the Fellowship, 1, Wimpole-street, London, W. 1.

CANCER HOSPITAL.—The committee of the Cancer Hospital in the Fulham-road is appealing for money for extensions, the first part of which will be wards for "middle-income" patients who can contribute to their upkeep.

NOTTINGHAM GENERAL HOSPITAL.—At the 145th anniversary meeting of the governors it was stated that one-half of the population of the city and county subscribes in some way or other to the funds of the hospital.

BUXTON COTTAGE HOSPITAL.—The Duke of Devonshire has given the necessary land for the extension of the Buxton and District Cottage Hospital. The new wing, with day wards for children and provision for sunlight treatment, will cost about £6000.

LONDON SCHOOL OF MEDICINE FOR WOMEN: ANNUAL DINNER.—The annual dinner of the London (Royal Free Hospital) School of Medicine for Women was held on Thursday, Dec. 1st, at the Savoy Hotel, Dr. A. G. Phear, the senior physician to the hospital, presiding over a large gathering, 414 diners being present. As the annual function was originated by Dr. Phear the fine attendance was fitting. Dr. Phear, in giving the Royal toasts, reminded the audience of the recent honour done to the hospital by the Queen, who opened the new children's ward.

The toast of Prosperity to the School and Hospital was proposed by Sir William Beveridge, Vice-Chancellor of the University of London and Director of the London School of Economics, who said that, apart from the drawback of having to make an after-dinner speech, he was delighted to address such an audience as was present. He would confine his remarks to the relations which the school bore to the University of London, leaving the details of progress in hospital and school to be stated in the reply from the chairman. The school, which had been and was splendidly successful, formed, he said, an integral part, more than any other of the medical schools of the metropolis, of the University of London, which was the largest University in the Kingdom and the first to recognise in any full way the claims of women upon university teaching. He considered that the acquisition of the Bloomsbury site was of the highest importance for the life of the University, and he hoped that, when that site was properly defined and when suitable buildings were placed upon it, the whole area would be transformed into an academic quarter. London, he pointed out, had a Government quarter in Whitehall and a commercial quarter in the City of London and the docks; Bloomsbury with its fitting university buildings would form an academic quarter. And of those buildings he hoped that one of the first to be erected would be a great hall of assembly, in which the University could hold its receptions and celebrations and accommodate hospitable gatherings like the present one, while it would be convenient for such recreative purposes as examinations. He wished both the school and the hospital all prosperity.

Dr. Phear, who warned speakers to follow him that the ideal duration of an after-dinner speech was ten minutes, noted the acquisitions during the year to the staff as having been unusually numerous, while in reference to their losses he spoke in warm terms of the great and quiet services which had been rendered by their late chairman, Dr. Alfred Langton. Langton had given of his personal means, seeking neither reward nor recognition, resembling in both respects their late and lamented friend, Dean Aldrich-Blake. With regard to the academic successes of the school he said that they were monotonous and sometimes to himself, as to his colleagues at the hospital, amazing. Considered from the point of view of hospital workers, the students in the school, and their teachers also, appeared to have abundance of time for recreation. He showed, however, that he thought opportunities for recreation should go hand-in-hand with work, for he pointedly referred the question of certain lawn-tennis courts, to be used by the staff of the hospital as well as by the school, to the kind consideration of the chairman of the hospital, Lord Riddell, who was present.

The toast of the numerous guests was proposed by Dr. Gertrude Dearnley, gynæcological surgeon to the hospital, who confessed to an ingenious method of dealing with the difficulty of numbers. She had, she said, drawn the names of the guests from a hat and proposed to deal with them in the order in which those names had emerged so as to avoid invidiousness, for all the guests fell under the one category of being the friends of the Royal Free Hospital and of the school attached. She ran through the list with kindly comment and coupled the toast with the names of Sir StClair Thomson and Lady Greenwood, when both the responses were made on humorous lines.

The health of the chairman was proposed by Dr. Janet Aitken, who mentioned Dr. Phear's support for 25 years of the Choral Society, as one of his many claims to their gratitude. After a brief reply from Dr. Phear the company adjourned to the neighbouring ball-room, where a dance had been arranged. This proved a fitting close to a thoroughly pleasant function.

A LEAGUE OF SUBSCRIBERS.—Since the League Subscribers to Edinburgh Royal Infirmary was started 1919 the total sum obtained by its efforts is £159,0 There are now 1418 contributing groups, 1034 of which in Greater Edinburgh.

AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION.—The winter dinner of this association in Engl will be held on Dec. 16th, at 8 P.M., at the Trocadero Restaurant, Piccadilly. The High Commissioners for Austr and New Zealand will be the official guests. The hon secretaries are Mr. E. T. C. Milligan and Mr. H. Bed Russell, 86, Harley-street, London, W. 1.

MIDDLESEX HOSPITAL.—The annual report st that there were 5319 admissions in 1926, that the ave stay of patients was 22 days, and that the average per in-patient was £15 15*s.* 9*d.* The new cases treated the out-patient department numbered 45,457, and out-patient attendances were 197,825. The income £82,113, and the expenditure £97,315. The first par the reconstruction scheme has cost over £400,000.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

FUTURE OF VOLUNTARY HOSPITALS: IMPORTANT ANNOUNCEMENT.

ON Thursday, Dec. 1st, in the House of Commons, Roy WILSON asked the Minister of Health whether, in proposals for the reform of the Poor-law and reorganisa of the health services of the country, he contemplated the voluntary hospitals should or would come under control of the State or the local authorities.

Mr. CHAMBERLAIN replied: No, Sir, on the contra regard the preservation of the Voluntary Hospital sys as a matter of essential importance in the health inter of the country. What has been impressed on my m is the absence as a general rule at present of any syste arrangements for coöperation in the various areas of country between the voluntary hospitals and the hosp and institutions carried on by the local authorities have, therefore, suggested that it is advisable that should be consultation in the various areas with a vie arriving at an agreed plan for institutional provision w would enable each kind of hospital to play its proper in meeting the ever-increasing need of the people for pital accommodation. I should anticipate that u such a plan the position of the Voluntary Hospitals w be strengthened and not weakened, but I have never templated putting any compulsion upon them to come an arrangement, their participation in which would matter for their own determination.

Mr. WILSON: In view of the widespread apprehen in the minds of those responsible for voluntary hosp in this country, who hold the impression, rightly or wro that the right hon. gentleman does mean to bring volun hospitals in some way under the local authorities, wil be good enough to give the widest publicity possible to very important statement which he has made in an to my question?—Mr. CHAMBERLAIN: I hope the fact I have made the statement will have the effect of gi wide publicity to it.

Mr. MONTAGUE: Why does the right hon. gentleman that the health interests of the country are bound up the voluntary system?—Mr. CHAMBERLAIN: That is ra a big question to be dealt with by question and answer.

Mr. BARKER: Is the right hon. gentleman aware the voluntary hospital at Blaina is almost closing for of funds, and in these cases in necessitous areas wil Department relieve the hospitals?

Mr. LUNN: Has the right hon. gentleman considered dreadful financial position of voluntary hospitals in parts of the country to-day and the failure of volun hospital boards to extend to meet the requirements of many waiting patients; and will the Government cons giving further funds to the Cave Commission so that can further assist voluntary hospitals in their difficulties

Mr. CHAMBERLAIN: I think a review of the circumsta of voluntary hospitals during the past 12 months will s that they have responded in an astonishing manner to requirements of the country, and while at one time it appear to be impossible for them to meet the need extension, they are, I am very glad to say, now la overcoming that difficulty; and not only have they able to find in most cases sufficient money for the m tenance of the existing beds, but they have even been to make very considerable additions.

MEDICAL PRACTITIONERS' PRIVILEGE.

The text of Dr. GRAHAM LITTLE's Bill to provide that rtain communications between medical practitioners and eir patients shall be privileged from disclosure in evidence, s now been issued. It runs as follows :—

1. Any information obtained by a duly registered medical actitioner from any patient treated for venereal disease ıder a scheme approved in pursuance of Article 11 (2) of e Public Health (Venereal Diseases) Regulations, 1916, R. & O., 1916 (No. 467), shall be regarded as confidential, d shall be privileged from disclosure in a court of law : ovided that the information obtained shall have been tained for the purpose of a cure, or assisting in a cure, of person so treated : And provided also that this privilege all not extend to any communication made with the ject of committing or aiding in committing any fraud or me.

2. For the purpose of this Act " duly registered medical actitioner " shall mean a person whose name is on the Medical Register."

3. This Act shall be called the Medical Practitioners' mmunications Privilege Act, 1927.

The Bill was read a first time on Nov. 22nd.

HOUSE OF LORDS.

MONDAY, DEC. 5TH.

CLEARANCE OF SLUM AREAS.

The Bishop of SOUTHWARK asked His Majesty's Govern- ent when they proposed to introduce legislation to cilitate the clearance of slum areas. He said that it had en understood that the policy of the Ministry of Health d the Government has been first to build new houses and en when sufficient new houses had been built to deal with m areas. They were all bound to acknowledge that so in this policy the Government had been most successful. er a million houses built since the war was an achievement ich did great credit to the Minister of Health and those rking with him, but it was just because so many houses d been built that it was now opportune to ask when steps uld be taken to deal with the slum areas. The slums of e country were so large in extent and so terrible in their nditions that they might very easily prove a real menace the welfare of the nation. The London County Council d schemes relating to 91 acres which would affect 25,000 ople. But quite apart from the people who would be ected by these schemes, it was estimated that there were fewer than 11,500 houses which were insanitary and ntained a population of over 100,000. Some figures could obtained from the annual statistics of the medical officers health. In the borough of Southwark there were 10,000 uses, in the borough of Deptford 4000 houses, in the rough of Battersea 3000 houses, and in the borough of estminster 841 houses, which were not in all respects sonably fit for occupation. A large number of them were sanitary. Out of London in such towns as Bristol, verpool, Glasgow, Nottingham, Bradford, and Leeds the nditions were just as serious. From statements he had ceived from competent observers in his diocese he could e a case of one street of 23 houses in which all the houses re overcrowded. The existence of slums meant that a ry large portion of the population had to grow up under nditions in which health was almost impossible, in which e education of the elementary schools was thrown away, here home-life could not be really experienced, and where aracter as well as physique was almost bound to teriorate. He thought that they were bound to admit that ere were some people who had what was called " the slum nd." They could not wonder at it, when people had en born and brought up in these surroundings. But those o knew the facts best were prepared to testify that these re after all in a small minority. Move people into better roundings, give them a better chance, and almost at once ey would see a change. He admitted that local authorities eady possessed large powers in regard to slum clearances d that in a number of cases they were using their powers mirably. But when they had taken into consideration erything that had been done the fact still remained that e greater part of the slums remained untouched. At the esent rate of progress another generation would grow up d die in the slums, and new slums would have been ated before the old slums had been abolished. Apparently arge number of authorities were taking no steps whatever deal with the slums. He knew that the difficulties in the y of local authorities were great. The cost of slum arance was very great, and the local authorities, which a rule had the greatest problem in this respect were those ich were financially the least able to meet it. It might be cessary to adopt some temporary measure which, while ognising that slum clearance was the ideal solution of e problem, would enable people to live in or near their esent homes under different conditions.

The Bishop of LONDON said he attributed a great deal of social unrest in the country to bad housing conditions. Overcrowding was the parent of disease. He hoped to hear from the Government that they fully realised the appalling nature of the problem and would give all the help they could towards solving it.

Viscount GAGE, Lord-in-Waiting, replying on behalf of the Government, said that although the efforts of the Government and local authorities since the Armistice had been mainly concentrated on the provision of new houses, it must not be thought that the clearance of slum areas had been entirely neglected. In fact the progress made, having regard to the difficult circumstances, could be described as encouraging. Since the Armistice 105 schemes had been confirmed by the Minister of Health and others were under consideration. In the 24 years prior to the war—that was after the passing of the Housing Act of 1890, which gave local authorities the power to deal with slums—only 44 reconstruction schemes dealing with small areas were confirmed. The schemes, which had been confirmed since the end of the war, were spread over England and Wales and involved the demolition of a considerable number of properties and the provision of new houses for a large number of people. The London County Council had been particularly energetic in tackling the slum problem and had a definite programme in operation under which the worst areas were being dealt with in order of urgency. They had made substantial progress since 1919. Eleven schemes of considerable magnitude had been confirmed. In addition to this the City Corporation and the metropolitan boroughs had received confirmation of a further 12 schemes, making in all 23 schemes for the metropolis. Other large schemes were also under consideration for London. An Exchequer subvention of one-half of the estimated average annual loss on slum schemes, including the cost of rehousing, was available for local authorities who undertook schemes. Apart from the wholesale clearance of large slum areas it should not be forgotten that local authorities were paying constant attention to the condition of individual houses in their districts. He would like to quote some figures regarding the remedial work done which were taken from the reports of the medical officers of health for 1925. There had been 1,114,000 houses inspected by officers of the local authorities. Of these 244,000 were rendered fit by the owners after service of statutory notices ; 5000 were made fit by the local authorities in default of the owners, and defects were remedied in the case of 279,000 houses without the need of formal action. Thus the local authorities were able to secure repairs in 528,000 cases during the year. He was authorised by the Minister of Health to state that he considered that this problem must be tackled in a much more comprehensive manner if any considerable improvement was to be effected within a reasonable time. There was no doubt that the very large numbers of new houses which were now being completed annually must ultimately—and it was hoped in the near future—relieve the overcrowding problem ; and the time should not be far distant when local authorities would be in a position to turn their attention in a greater degree to the slums. The Minister had come to the conclusion that although the powers of local authorities for dealing with slums at present were wide and far-reaching it might be possible to introduce a further measure which should be practical and effective in helping those people who were now living in such unsatisfactory conditions. The scheme which was at present under consideration was one whereby houses in an unsatisfactory area which might be saved by the expenditure of a little money would be reconditioned, and only houses which were past redemption would be demolished. By the judicious use of powers on these lines a bad area might be opened up and improvements effected in a much shorter time than it would take to clear the whole area and rehouse the whole population of the area. Another matter on which the Minister had promised to legislate was in regard to the basis of compensation payable for insanitary property acquired in connexion with slum schemes. The Minister was not at present in a position to indicate precisely the time or the nature of the legislation ; but the matter was receiving most earnest consideration, and the Minister would make a statement on the subject when his proposals were in a more definite form.

TUESDAY, DEC. 6TH.

Course of Parliamentary Business.

The Marquess of SALISBURY, Lord Privy Seal, in the course of a statement as to the Parliamentary business which the Government hoped to get through before Christmas, said that in addition to the principal Government measures there were one or two other smaller Bills which it would, no doubt, be in the interests of the country to get through if possible. He spoke of them only in a doubtful sense, but these measures included the Road Transport Lighting Bill, the Mental Deficiency Bill, and the Nursing Homes Bill. These Bills were not yet through the House of Commons,

but if they were quite non-contentious in their Lordships' House, perhaps the Government might ask them to agree to them.

Royal Edinburgh Hospital Bill.

The Royal Edinburgh Hospital for Mental and Nervous Diseases Order Confirmation Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 30TH.

Trade in Derivative Drugs.

Mr. DAY asked the Secretary of State for Foreign Affairs which members of the Council of the League of Nations had ratified the suggestion that a central board should be established to assess and ration the trade in derivative drugs.—Sir A. CHAMBERLAIN replied: The appointment of a Permanent Central Board to "watch the course of the international trade" in opium and other dangerous drugs is provided for in Chapter VI., Articles 19 to 27 of the Geneva Opium Convention of 1925. A ratification of that Convention has been deposited on behalf of His Majesty covering all parts of the British Empire other than Canada and the Irish Free State. Of the other States at present members of the Council only France and Poland have ratified.

Treatment of Rheumatism.

Mr. HARDIE asked the Minister of Health whether he could give any indication by figures as to the number of people suffering from rheumatism; and whether he contemplated establishing treatment similar to that provided for tuberculosis.—Sir KINGSLEY WOOD, Parliamentary Secretary to the Ministry of Health, replied: As regards the first part of the question I do not think it practicable to give figures for the general population, though I may say that the annual rate of attack for rheumatism of all kinds among the insured population was estimated in 1924 as 27 per 1000. As regards the second part of the question, some progress is being made in the larger cities towards the provision of treatment for patients of certain classes, especially children, suffering from acute and subacute rheumatism. Such schemes are being carefully watched by my officers, but as at present advised, my right hon. friend would not feel justified on public health grounds in contemplating treatment of rheumatism by means of a general scheme on the lines of that adopted for tuberculosis.

Poor-law Guardians and Isolation Wards.

Mr. GROVES asked the Minister of Health whether he was aware that the Lambeth board of guardians reported, in July, 1920, that they could offer no suggestion which would secure the provision of suitable accommodation for isolation and observation purposes; and whether as no steps had yet been taken to comply with the requests of his department, he proposed to take any action, and, if so, what.—Sir KINGSLEY WOOD replied: My right hon. friend has been in correspondence with the board of guardians over a considerable period in regard to the provision of isolation wards in their infirmary. The guardians have not, at present, seen their way to make this provision, and they decided recently, after an investigation by a committee, to defer further consideration of the matter for six months. The question of the action to be taken is receiving my attention, and my right hon. friend is obtaining a report on the present position from one of his medical officers.

Early Notification of Tuberculosis.

Dr. VERNON DAVIES asked the Minister of Health if he was satisfied with the present position in regard to the early notification of tuberculosis in this country; and, if not, whether he proposed to take any steps to impress upon medical practitioners and the community the vital importance of early notification of this disease both to the public health and to the patient.—Sir KINGSLEY WOOD replied: My right hon. friend is not yet satisfied that the early notification of tuberculosis has been secured in all parts of the country. Circulars have already been issued by my right hon. friend's department to medical practitioners and local authorities on this subject, and the present position is described on pages 40 and 41 of the last Annual Report of the Department. The position will be again considered on the receipt of the notification returns for the present year.

State Payments to the G.M.C.

Mr. BECKETT asked the Minister of Health what State payments were made to the Medical Council during 1926; and for what purpose.—Major Sir G. HENNESSY replied: I am informed by my noble friend, the Lord President of the Council, that no State payments were made to the General Medical Council during 1926; as a matter of fact, no State payments are made to that body.

Foot-and-Mouth Disease and Public Health.

Dr. VERNON DAVIES asked the Minister of Agricult if he was aware that, for the sake of the public health, authorities of the United States of America had pla restrictions upon the import into that country of So American meat from sources infected with foot-and-mo disease; and would he consider the desirability of discu ing this aspect of the question with the Minister of Hea so as to be sure that the health of the people of this coun was adequately safeguarded.—Mr. GUINNESS replied: order was issued by the United States Department of A culture on Sept. 17th, 1926, which prohibits the impo tion of fresh or frozen beef, veal, mutton, lamb, or p from countries in which rinderpest or foot-and-mo disease exists, in order to prevent the introduction of contagion of such diseases into the United States. order appears to be designed to protect animals, beca human beings do not suffer from rinderpest. I am inform by my right hon. friend the Minister of Health that pra cally all meat imported into Great Britain from So America is examined and passed by Government inspect of the countries of origin, and is subject to further inspect on arrival in this country.

Dr. DAVIES: Is it the opinion of the Ministry of A culture that there is no danger to human beings in allow meat which may be contaminated with foot-and-mo disease to come into this country?—Mr. GUINNESS: the practice is to cook meat before people eat it I do think that there is much danger. The recorded cases foot-and-mouth disease have been traced to milk or cont with diseased animals. I do not think there is any evide in the case of cooked meat.

THURSDAY, DEC. 1ST.

Pensioners and Hospital Deductions.

Mr. MELLER asked the Minister of Pensions whether was aware that it was the practice in calculating the amo deducted from pensions in respect of hospital treatme for the period during which the recipient was underg such treatment, to count broken periods of less tha week as a full week; whether he had received compla in respect of such deductions; and whether he would t steps to see that in future such deductions were only m for the appropriate number of days of the broken perio Major TRYON replied: Payments under Article 6 of Royal Warrant and any necessary adjustments in connex with them are made on a weekly basis. I am satisfied t this practice which has always obtained under the warr is on the whole of advantage to pensioners and makes convenience of administration. I am looking into working of the rule in exceptional cases of the type wh my hon. friend has brought to my notice.

Mr. R. MORRISON: Is the right hon. gentleman aw that in some cases when a man is in hospital for nine d a fortnight's allowance is deducted. Is that not rat unfair?—Major TRYON: It is not, as a rule, a case of ded tion. In the great majority of cases the men in hosp are better off financially than those not in hospital.

New Health Insurance Legislation.

Sir RICHARD LUCE asked the Minister of Health whet he was now in a position to make any statement as to steps to be taken to give effect to the recommendation of the Royal Commission on National Health Insurance a in particular, those relating to the abolition of insura committees and the provision of a specialist and consult medical service for all insured persons by means of a par pooling of future surpluses of approved societies.—Mr. CHAMBERLAIN replied: The various recommendations of the Royal Commission have now been exhaustively cussed with the Consultative Council of Approved Societ and it is intended pursuant to that discussion to take first convenient opportunity of introducing an amend Health Insurance Bill embodying most of the recommen tions of the Royal Commission. It is not, however, p posed to provide in this Bill for the abolition of insura committees or for the extension of medical benefit to incl a specialist and consultant service by means of a par pooling of societies' surpluses.

Food Value of Fresh Milk.

Mr. HURD asked the Minister of Health whether, in interests of public health, he would take measures to g the widest publicity to the high food value of fresh liq milk for adults as well as children, as compared with mach skimmed condensed milk.—Mr. CHAMBERLAIN replied should be glad to see an increased consumption of fr liquid milk, on account of its high nutritional value, an am assured that a potent factor in bringing this abou to continue to improve its cleanliness, wholesomeness, general acceptability. A publicity campaign is at pres being conducted on the subject, with which I am fully sympathy, and I may also say that I understand that

Empire Marketing Board have the question of milk publicity under consideration at the present time.

Inspections under Food and Drugs Act.

Dr. VERNON DAVIES asked the Minister of Health if he would give for the last three years for which statistics were available the number of inspections under the Food and Drugs Act; the number of samples analysed; the percentage of adulterations; and the number of prosecutions in England and Wales.—Mr. CHAMBERLAIN replied: I have no record of the number of inspections made or prosecutions undertaken under the Sale of Food and Drugs Acts. The following is a statement showing the number of samples analysed under the Acts, the number reported to be adulterated and the percentage of adulterations in England and Wales for each of the calendar years 1924, 1925, and 1926.

Sale of Food and Drugs Acts.

	1924.	1925.	1926.
No. of samples analysed	118,000	118,930	120,617
No. of samples adulterated	6,987	7,714	7,044
Percentage of samples adulterated	5·9	6·5	5·8

MONDAY, DEC. 5TH.

Provision of Meals of School-children.

Sir WILLIAM EDGE asked the President of the Board of Education whether, according to advices which had reached him, special efforts would be needed this winter in feeding children at school; and whether he had issued any circular on the subject to local authorities.—Lord E. PERCY replied: No, Sir; generally speaking, the returns which are now being received from local authorities show the usual seasonal increase in the number of children provided with meals. The authorities appear to be watching the situation in their areas closely, and there does not seem to be any need to issue a circular.

TUESDAY, DEC. 6TH.

Foot-and-Mouth Disease and South American Meat.

Dr. VERNON DAVIES asked the Minister of Agriculture if any meat had arrived in this country from South America in recent years showing evidence of foot-and-mouth disease; if so, what representations, if any, had been made to the South American authorities as to the lack of efficiency of their inspection before shipment to this country; and if any such meat had escaped the vigilance of the inspectorate in this country at the port of arrival here.—Sir KINGSLEY WOOD replied: No instance of suspected foot-and-mouth disease in meat imported into this country from South America has been reported, although the inspectors at the ports of arrival have for many years examined meat for evidence of this disease. My right hon. friend is not aware of any authenticated evidence that meat affected with foot-and-mouth disease escaping the vigilance of the inspectors at the ports.

Services of Tuberculosis Officers.

Mr. DAY asked the Minister of Health whether his attention had been called to the special notice issued by the public health committee of the Devon county council to the effect that they wished to make it quite clear that the tuberculosis officers were absolutely free to all classes of the community, and that in no case could remuneration be made to them in any form; and whether there were any reasons for the issue of this notice.—Sir KINGSLEY WOOD replied: My right hon. friend is informed by the county council that their Public Health Committee have passed a resolution substantially in the terms stated by the hon. Member. A copy of the resolution has been sent to the officers concerned, but no other steps have been taken to make it public. My right hon. friend is informed that the resolution was passed because it was reported to the committee that one or more of the tuberculosis officers of the county council had in fact received fees or presents from individuals visited by them in their capacity of tuberculosis officers.

Deficiency of Fat in Condensed and Dried Milk.

Brigadier-General CLIFTON BROWN asked the Minister of Health whether his attention had been drawn to a recent report of the Ministry of Health, which stated inter alia that several samples of condensed and dried milk were reported against as deficient in fat, and the analysis in the case indicated that the article sold as dried milk consisted of soya bean, cane sugar, milk sugar, and a vegetable oil; what action had been taken in the matter; and in what countries were these articles produced.—Sir KINGSLEY WOOD replied: The report in question is the annual report of the Ministry of Health for 1926–27. In the particular case mentioned the vendor was prosecuted and fined. Deficiency of fat was found in 26 of the 1310 samples of condensed and dried milks taken by local authorities. In three of the cases the vendor was prosecuted and fined and in other cases warnings were given. My right hon. friend has no information as to the country of origin of the samples taken.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Dec. 12th.—5 P.M., WAR. Paper: Wing Comdr. T. S. Rippon, R.A.F.: The Danger Instincts.

TUESDAY.—5 P.M., THERAPEUTICS. Discussion on the Action of Synthalin, to be opened by Dr. H. H. Dale and Dr. George Graham. Other speakers: Dr. R. D. Lawrence and Prof. H. MacLean. 8.30 P.M., PSYCHIATRY. Paper: Dr. Millais Culpin: A Study of the Minor Psychoses: their Clinical and Industrial Importance. NEUROLOGY. Members of the Section of Neurology are specially invited to attend this meeting.

WEDNESDAY.—LIBRARY. The main Library will close at 5 P.M., but readers will be accommodated in other rooms until 6.30 P.M. 8.30 P.M., SOCIAL EVENING. From 8.30 to 9 P.M. Fellows and guests will be received in the Library by the President and Lady Berry. At 9.30 P.M. Sir Alexander Houston, Director of Water Examinations, Metropolitan Water Board, will give an address entitled "The Romance of London's Water-supply," to be followed by demonstrations. A number of exhibits will be on view. Music and light refreshments.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Cases: Dr. H. W. Barber: (1) Von Recklinghausen's Disease with the "Forme Fruste" in Three of the Patient's Children. Dr. H. MacCormac: (2) Xanthoma; (3) Chancre Redux with Negative Provocative Test. Demonstration: A polychromide film, showing the present possibilities of colour cinematography, will be shown after the discussion of the cases.

FRIDAY.—8 P.M., OBSTETRICS. Specimens: Dr. W. G. Barnard: (1) An Endotheliomatous Dermoid of the Ovary; (2) Sarcoma Arising in the Cervical Stump. Mr. Frederick Roques: Endometriomyoma of the Umbilicus. Prof. Beckwith Whitehouse: Menstruation Through a Laparotomy Scar for Twenty Years, Associated with Diffuse Endometriomatosis of Pelvic Cavity of Abdominal Wall. Paper: Mr. Burt-White: An Investigation into the Ætiology of Puerperal Sepsis. 8.30 P.M., ELECTRO-THERAPEUTICS. Papers: Mr. E. W. Twining: On Interlobar Pleurisy (with special reference to mediastino-interlobar effusion). Dr. C. G. Teall: A Radiological Study of the Bone Changes in Renal Infantilism.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Dec. 12th.—8.30 P.M., Discussion on Insomnia, to be introduced by Dr. Eustace M. Callender, followed by Dr. Gordon Holmes and Sir Maurice Craig.

CHELSEA CLINICAL SOCIETY.

TUESDAY, Dec. 13th.—8.30 P.M. (at the Hotel Rembrandt, Thurloe-place, S.W.), Mr. P. Jenner Verrall, Mr. A. G. Timbrell Fisher, and Mr. S. L. Higgs will open a discussion on Orthopædics in General Practice. The meeting will be preceded by dinner at 7.30 P.M.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich, S.E.

FRIDAY, Dec.9th.—8.45 P.M., Mr. Victor Bonney: Puerperal Sepsis (Purvis oration).

EUGENICS SOCIETY.

WEDNESDAY, Dec. 14th.—8.30 P.M. (in the rooms of the Royal Society, Burlington House, W.), Sir Bernard Mallet: Problems for Research Arising out of the Population Conference.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Dec. 12th, to SATURDAY, Dec. 17th.—FELLOWSHIP OF MEDICINE. Lecture at Medical Society, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Mr. Ernest Clarke: Practical Hints in the Correction of Errors of Accommodation and Refraction of the Eye.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Special course, afternoons only, second week. Tues., special demonstration by Dr. Haldin-Davis.—INFANTS HOSPITAL, Vincent-square, S.W. Afternoon course, second week.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Last week of post-graduate course in neurology; every afternoon at 5 P.M. Further information from the Secretary, Museum 2236.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, W.

MONDAY, Dec. 12th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Dr. Trevor Davies: Gynæcological Department.

TUESDAY.—11 A.M., Mr. Endean: Demonstration of Venereal Diseases. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 4.30 P.M., Mr. Donald Armour: Head Injuries (lecture).

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. MacDonald: Genito-urinary Department. 2 P.M., Mr. Bishop Harman: Eye Department. 4.30 P.M., Dr. Pritchard: Intravenous Treatment (lecture).
FRIDAY.—10 A.M., Dr. Pritchard: Special Medical Treatment Clinic. 12 noon, Dr. Redvers Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.
Medical and Surgical Out-patients, Operations, Special Departments, daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
WEDNESDAY, Dec. 14th.—4 P.M., Major Meurice Sinclair: Clinical Demonstration of Fracture Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Dec. 12th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
There will also be a special demonstration of medical cases on Mon., Dec. 12th, at 2 P.M., and of surgical cases on Fri., Dec. 16th, at 2 P.M., by Dr. A. J. Whiting and Mr. E. Gillespie respectively.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Dec. 13th.—3.15 P.M., Dr. A. Lisle Punch: Asthma.

BELGRAVE HOSPITAL FOR CHILDREN, 1, Clapham-road, S.W.
WEDNESDAY, Dec. 14th.—4.30 P.M., Clinical Meeting, conducted by Dr. M. S. Thomson.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
WEDNESDAY, Dec. 14th.—4 P.M., Demonstration of Interesting Cases.
FRIDAY.—4 P.M., Mr. Watkyn-Thomas: Pre-cerebellar Cysts.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Dec. 13th.—5 P.M., Dr. S. E. Dore: Erythemato-squamous Eruptions.
THURSDAY.—5 P.M., Pathology Demonstration.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Dec. 13th.—4.15 P.M., Mr. H. H. Rayner: Surgical Diathermy.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Dec. 16th.—3.30 P.M., Dr. Grout: Radiology in Diagnosis.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Dec. 13th.—4 P.M., Prof. R. Muir: The Dissemination of Malignant Disease, with special reference to the Abdomen. Discussion to be opened by Dr. J. Anderson.
FRIDAY.—4 P.M., Case Reading and Discussion, in which all medical practitioners are invited to take part.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Dec. 14th.—4 P.M., Prof. E. W. Hope: The Changed Conditions of Quarantine.

PEOPLE'S LEAGUE OF HEALTH.
THURSDAY, Dec. 15th.—6 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. H. Crichton-Miller: Development and Function of Mind.

Appointments.

BROOKE, R., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Hon. Orthopædic Surgeon to the Royal West Sussex Hospital.
COMBE, W., M.B., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts (Snodland District, Kent).
HALL, G., M.D., F.R.C.P. Lond., Honorary Physician, Royal Victoria Infirmary, Newcastle-on-Tyne.

Vacancies.

For further information refer to the advertisement columns.
Ancoats Hospital Convalescent Home, Great Warford, Alderley Edge.—Hon Visiting Phys. £50.
Barnsley, Beckett Hospital and Dispensary.—Sen. and Jun. H.S.'s. £220 and £140 respectively.
Basingstoke, Park Prewett Mental Hospital, nr. Basingsto Hants.—Med. Supt. £950.
Birmingham and Midland Homœopathic Hospital and Dispensa H.S. £150.
Birmingham Union, Dudley-road, and Selly Oak Hospitals Pathologist. £750.
Bolton Infirmary and Dispensary.—H.S. £150.
Chichester, Graylingwell Mental Hospital.—Jun. M.O. £300.
Croydon County Borough.—Asst. M.O.H. for Tuberculosis. £7
Derby, Derbyshire Royal Infirmary.—H.S. for Ear, Nose, a Throat Dept. £150.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at r of £110.
East Sussex Administrative County.—County M.O.H. £1200
Exeter, Wonford House Hospital.—Med. Supt.
Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.
French Hospital and Dispensary, 172, Shaftesbury-avenue, W.C Asst. Pathologist. £100.
Hampstead General and North-West London Hospital, Haverst Hill, N.W.—Cas. Surg. O. and H.S. Each at rate of £1
Hove Hospital, Sackville-road, Hove.—Res. M.O. £150.
Huddersfield Royal Infirmary.—Jun. H.S. £150.
Hull Royal Infirmary.—Res. House Governor. £500.
Infants Hospital, Vincent-square, Westminster.—Patholog £600.
Ipswich, East Suffolk and Ipswich Hospital.—H.S. Also Cas. Each £100.

London Hospital, E.—Cardiographic Dept. Paterson Resea Scholar. £400.
London Temperance Hospital, Hampstead-road, N.W.—Cas. At rate of £120. H.P. At rate of £100. Med. Reg. 40 g
Manchester, Ancoats Hospital.—H.S. At rate of £100. A Anæsthetists. 10*s.* 6*d.* per attendance.
Manchester, Victoria Memorial Jewish Hospital, Cheetham Hon. Asst. Phys.
Miller General Hospital for South-East London, Greenwich-ro S.E.—H.S. £125.
Nelson Hospital, Merton, S.W.—Res. M.O. At rate of £100.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst.
Portsmouth Royal Hospital.—Cas. O. At rate of £100.
Prison Medical Service.—M.O., Class II. £350.
Royal Waterloo Hospital for Children and Women, Waterloo-ro S.E.—H.P. At rate of £100.
St. Pancras Hospital, &c.—Jun. Asst. Med. Supt. £350.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Gard W.C.—Clin. Assts.
St. Thomas's Hospital.—Phys.
Salford Royal Hospital.—Res. Surg. O. £200. Also two H.S H.P., and Cas. H.S. Each at rate of £125.
Sheffield, Children's Hospital.—Res. H.S. £100.
Sheffield, King Edward VII. Hospital, Rivelin Valley-road H.S. At rate of £75.
Shrewsbury, Royal Salop Infirmary.—H.S. £200.
Torquay, Torbay Hospital.—Res. M.O. £200.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. Jun. Non-Res. H.S.'s. At rate of £150 and £100 respectiv
Willesden General Hospital, N.W.—Vacancy on Hon. Med. St
Wolverhampton and Staffordshire Hospital.—Resident Anæst tist. At rate of £100.

The Chief Inspector of Factories announces a vacant appointm t for a Certifying Factory Surgeon at Folkestone (Kent).

Births, Marriages, and Death

BIRTHS.

GRANT.—On Nov. 27th, at Barkston-gardens, S.W., the wif of Major J. F. Grant, R.A.M.C. (retired), of a daughter.
HILL.—On Dec. 1st, at Dalestead, Caterham Valley, Surrey, e wife of F. T. Hill, M.C., M.R.C.S., M.R.C.P., of a son.
TURNER.—On Nov. 26th, the wife of Terence Turner, M.R.C of The Bolt, Windsor Forest, of a daughter.
VEVERS.—On Nov. 22nd, at "Lavalance" Nursing Home, wife of Oswald H. Vevers, M.R.C.S., L.R.C.P. Lond., a son.

MARRIAGES.

JACK—DARLING.—On Dec 1st, at St. George's U.F. Chu Edinburgh, Donald Jack, L.R.C.P. & S., to Anne, you daughter of the late Dr. T. Brown Darling, Edinburgh.
THUNDER—NORTHALL-LAURIE.—On Nov. 26th, at St. Jam Spanish-place, W., Wilfrid Michael Thunder, M.B., Ipoh, Perak, F.M.S., to Eileen Frances, youngest daug of the late Reginald Peter Northall-Laurie, and of M Northall-Laurie, of Albion-street, Hyde Park, W.

DEATHS.

FOULDS.—On Dec. 4th, Francis Henry Foulds, M.R.C L.R.C.P., of Severn House, Droitwich Spa, aged 59 yea
LOMBARDI.—On Nov. 28th, suddenly, George Lombardi, L.I R.C.S. Eng.
NORBURN.—On Dec. 1st, following operation, Albert Norbu M.D., B.S. Lond., of Oldfield Park Lodge, Bath.
PIGGOTT.—On Dec. 1st, at "St. Wilfrid's," Mill Hill, Sudbu Suffolk, Edward Alfred Piggott, L.R.C.P., L.R.C.S. Ed formerly of Clare, Suffolk, aged 78.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notice Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SPINNERS' SCROTAL CANCER.

EXTRACT FROM ANNUAL REPORT FOR 1926.

BY JAMES ROBERTSON, M.B., C.M. GLASG., D.P.H.,
MEDICAL OFFICER OF HEALTH FOR DARWEN.

A Departmental Committee was appointed to "consider idence as to the occurrence of Epitheliomatous Ulceration ong Mule-Spinners" and to report to the Home Office. eir Report was published and circulated in April, 1926,[1] out four weeks after my printed thesis dealing with this bject. The Committee asked me for a synopsis of my rk and invited me to appear before them for discussion June 17th, 1925. At that date the detailed work I s engaged in being incomplete, the final facts and con- sions stated in my thesis were not then arrived at. In far as these completed facts and conclusions do not pport the Report I feel it my duty to offer the following nstructive criticism.

Findings of the Departmental Committee.

The Committee's Report is founded upon two principal guments:

First Argument.—That of Mr. A. H. Southam and the e Dr. S. R. Wilson, of Manchester,[2] namely: (*a*) that the spindles are oiled by mineral oil this oil is continuously ayed on to the spinner's overalls in the region of the otum; (*b*) that as the spinner pieces his broken ends must lean over the faller shaft; by so doing his scrotum nes into contact with this shaft, thereby causing friction. e oil, plus the friction, is the cause of the epithelioma.

Second Argument.—Dr. A. Leitch produced epithelioma n mice by rubbing mineral oil into their backs.

From these two arguments it is concluded that oil is the se of this disease. While I agree that mineral oil plus tion can be a cause of epithelioma, I feel satisfied that have definitely proved that neither the faller shaft, the ndles, bolster, or any part of the mule take part as a tor in the causation of this disease. As regards the ng of the spindles, the Committee's report and my ervations agree as to the facts, but differ as to the clusions to be drawn from them.

Exposure to Mineral Oil.

The Committee's Report (p. 17) says: "We have been ck by the different amounts of oil used in different mills the same type of mule. This apparently varies from a imum of ¼ pint to a maximum of slightly over 1 pint mule per day. We would suggest that in the interests economy and of cleanliness attention should be paid to ucing this to the minimum compatible with efficient rication. Our experiments show that owing to centrifugal on a large proportion of this oil is sprayed off during first few minutes after starting the machinery, but that asional drops are still being thrown off after two or even e hours. The oil is thrown from that portion of the e spindle immediately above the bearing, and normally does not appear to creep more than about 1/16 or ⅛ inch the spindle."

In my thesis I detailed experiments of repeated tests ch definitely established that all oil which is to be ayed off comes off within the *first three seconds*, and t the spinner cannot possibly be in a position to get of this spray upon his overalls. Apparently no actual s were made by the Committee as they are content to "the first few minutes." The quantity of oil thrown in three seconds has been found, by my experiments, e actually more than the Committee in their Report 18) states is thrown off—namely, my finding 1/10th pint per day per mule instead of the Committee's ing of 1/13th of a pint.

The Report further states: "That a quarter to one pint il per mule per day is used in the oiling and there are oilings." There are 9600 minim drops in one pint. the Committee's smallest computation, therefore, of nt of oil per mule per day there would only be 2400 minim s per mule per day or 1200 at each oiling, and as there 1320 spindles (p. 18) per mule, this means that each dle would get less than a drop per oiling, and if one s it at ½ pint per mule per day it would still be less than two drops per oiling, and as the spindles are revolving at 11,000 revolutions per minute it is difficult to take seriously the suggestion that these two drops or any part could be sprayed off for hours.

It must be remembered also that, when the oil is being sprayed off, that portion which is being sprayed towards the worker is only a quarter of the total spray circle. An equal amount will be sprayed off, of course, within the first three seconds towards the creel and to the right and left. I therefore contend that no oil can reach the spinner from the bolster or any part of the mule. My photographs further show very definitely that under no working conditions does the man's scrotum touch the faller shaft.

It may be stated that the whole theory of the faller shaft coming into contact with the spinner during the process of piecing breaks down in association with the spinners themselves. It is learned from them that when piecing is taking place to touch the faller shaft involves a loss of balance, and this happens to none except beginners. Just as the writer of the Committee's Report uses the phrase "first few minutes," in regard to the oil spray, so (p. 16) he states that the height of the bolster above the floor level is 2 feet 6 inches, whereas the exact height is 2 feet 3½ inches. This is material to our discussion, as if oil did spray from the bolster at a height of 2 feet 6 inches it would be at the scrotal level, but at 2 feet 3½ inches it is below the scrotal level. It is sufficient to say that all spinning mules are standardised.

As I have shown, the spinning mule can take no part as a factor in this disease, recommendations 2 and 3 given in the Report (p. 27) will add to expense and serve no purpose. These recommendations are: "(2) Development of a non-splash type of spindle bearing, more particularly for new mules; (3) prevention of oil splash from the spindles of existing mules by means of some form of guard, the type to be decided by a series of tests to be mutually agreed upon and arranged by the Masters' Federation and the Operative Spinners."

Although I have demonstrated that oil is not thrown on to the spinner from the spindles, oil however is found upon the overalls in two areas—namely, at the knees and down the flanks or thighs. This oil is received from the floor during the process of repairing any defects which may happen to the working parts of the mule. The spinner kneeling to carry out these repairs receives the oil direct upon his knees and when finished he wipes his hands down his flanks to dry off the oil before he does any piecing, as he must not oil-stain any thread. Most of the oil, however, is *received each Saturday morning* when the spinner has to clean every part of his pair of mules. After this cleaning up, which is the real dirty and oily part of his week's work, the spinner takes his dirty overalls home and returns on Monday morning with a clean pair. These facts are fully detailed in my thesis, as also the fact that by chemical analysis, while oil was determined to be present in the areas mentioned, no oil was found within the scrotal area. Scrotal sweat was, however, found by analysis in the fork area of overalls.

Reviewing all these facts, it cannot, in my opinion, be contended that because Dr. Leitch produced epithelioma under laboratory conditions upon mice with oil that similar laboratory conditions obtain in the mill under ordinary working conditions. Further, if this oil was cancerogenous, as the men work in bare feet, which are permanently oily, and under friction afterwards in their oily socks, there would be cases of epithelioma of the feet. I have heard of no such case amongst spinners, although I have seen several cases of epithelioma of the feet. Further, there are mills in Lancashire where women have always been employed as spinners, and no case of vulvar epithelioma is recorded. Neither does the oil theory explain the fact that 84 per cent. of these epitheliomas occupy an exactly similar site, the remaining 16 per cent. occurring upon a second specific site, as stated and explained in my thesis.

Chronic Irritation from Clothing.

Many observations which I have made since confirm my then stated opinion—namely, that the cause of spinners' scrotal cancer is due to the friction of the fork of the hard blue or white overall acting upon the scrotum each time the spinner leans over the faller shaft to piece, the fork being pulled up by the stretching movements of the body required by the piecing operation acting upon an inelastic brace. The aniline dye which stains the legs and scrotum, and the dirt on the latter, are aggravating factors. I suggest that the hard rough open seam at the overall fork produced irritation 200 to 240 times an hour 5½ days per week upon the scrotum at the specific sites of this disease, according to the spinner's reach in piecing his broken end. There are certain facts in the Committee's report which support my contention.

Total (22,699) ..	381	79	69	10	539	—

The districts marked with * changed to rough blue overalls about 1905, the other districts changed to rough white about 1905, but adopted the blue about 1917.

It will be noticed that the italicised figures (which have been added by me) in column 7 of the accompanying table giving the rate per 1000 spinners employed show a heavier rate in the Blackburn and Burnley areas. It was in these two areas only that the wearing of blue overalls commenced in 1905. Other areas did not adopt blue until 1917, but from about 1905 wore white overalls made of the same material in all respects except colour. The question does arise as to whether the aniline dye in the blue overalls added to the friction of the overall fork accounts in some measure for the increased incidence in these two areas. I stress the fact that the fustian overall was discarded in 1905 by some 90 per cent. of spinners, the present-day rough cotton material being used since that date. The very few cases of scrotal epithelioma during the years prior to 1905 and for some years afterwards did not exceed the average rate for the general population.

The Report states (p. 5): "We have also made some inquiries abroad as to whether there is evidence of a similar incidence amongst cotton mule-spinners, but, so far, replies from France, Germany, Russia, Poland, and America have led to entirely negative results. This is a little difficult to explain, but it must be borne in mind that the number of mule spindles in Great Britain is very much greater than the number in any other single country, that the number of persons employed abroad is consequently less, and that the number of cases likely to occur annually, if at all, would be very small."

The explanation I suggest for the absence of the disease in mule-spinners in the foreign countries mentioned is the fact that in those countries braces are not worn, but a belt only.

American Experience.

My theory has received confirmation from the following commentary added by Dr. Derric C. Parmenter to my article upon Spinners' Cancer in the *Journal of Industrial Hygiene* (June, 1927):—

"So far as I have been able to discover, cancer of the scrotum is relatively rare in the United States. Cases have been reported among men working with tar and with the paraffin oils, but these cases are few and not well defined. There seems to be very few recorded cases of cancer which are directly traceable to the cotton trades, such as spinners' scrotal cancer. This may be due to: (1) lack of observation heretofore; (2) the tendency of mill hands in the South to wear trousers with belts rather than shoulder-strap overalls; (3) the general tendency of mill hands in the North, the majority of whom wear overalls, to wear also some sort of underclothing.

"Any of these factors would undoubtedly tend to reduce the occurrence of anything like the spinners' cancer as discussed in Dr. Robertson's article. In Massachusetts at the present time an intensive study of cancer is being conducted by the State authorities, with special reference to its ætiology. This investigation should call attention to any types of cancer which may be of industrial origin. As yet, however, no definite conclusions have been reached."

Association with Ichthyosis.

After an address I gave to the Pathological Society at Manchester on spinners' scrotal cancer, Dr. L. Savatard showed a case of this disease, the patient also suffering from ichthyosis. We arranged to carry out some further investigations along this line, and Dr. Savatard permits me to publish the following extract from a paper he read to the Section of Dermatology, R.S.M., in May last:—

"What is the relative frequency of ichthyosis? It is apparently fairly common in Lancashire, but its incidence may vary in different parts of the country. In an examination of 400 operatives I have found a 5 per cent. incidence. Through the kindness of Dr. Robertson I have recently been afforded the opportunity of inspecting 400 mule-spinners at work. Their ages ranged from 15 years to 65 years and the duration of their occupation from two days to 50 years. I found 20 affected with ichthyosis. In ten the affection was slight and in the other ten the condition was well marked. Of these, two had suffered from scrotal cancer. Three presented keratotic lesions on the face and temporal regions. I saw no such lesions in the non-ichthyotics; hyperkeratosis of the palms was seen only in the ichthyotics. I could find no evidence of any dermatosis of an occupational character, unless it be two cases of mild folliculitis of the arms in two youths who were also affected with ichthyosis.

"As a result of this investigation I believe that ichthyosis is an important ætiological factor in mule-spinners' cancer. Though I do not deny that scrotal cancer does arise apart from ichthyosis, I am convinced that the great majority of such patients will give evidence of an ichthyotic skin.

"It is not my purpose to discuss the cause of scrotal cancer, but I would express my regret that the Department Committee as a result of its inquiry in 1925 should have found that 'in the absence of exposure to mineral oils there would be no mule-spinners' cancer.' I cannot help thinking that this conclusion was premature. Dr. Robertson, in a careful inquiry into this subject, comes to a very different conclusion."

Conclusion.

The experience gained in visiting a large number of mills makes me entirely agree with the Committee that much can be attained by regular medical inspection and advice. I am further of opinion that such inspection would rapidly secure personal hygiene amongst spinners, and thin itself would tend to lessen the incidence of this serious disease.

I also strongly recommend that braces should be discarded, and that belts be worn, and further, that the spinner should wash his thighs and scrotum with soap and water every night. By these means I am confident that this disease would be conquered.

IMMUNISATION AGAINST DIPHTHERIA.

AT a recent meeting of the Baby Week Council, Prof. H. R. Kenwood, who presided, maintained that diphtheria would be comparatively rare if children were to obtain the protection which immunisation by toxin-antitoxin provided. The method was no longer experimental, but had been tested and found capable of producing excellent results. Dr. C. C. Okell said that by means of the Schick test and active immunisation, diphtheria could be prevented with practical certainty, whilst Dr. R. A. O'Brien considered that the goal to be aimed at was the simultaneous protection of children against both diphtheria and scarlet fever by two small injections which would not interfere with their ordinary health and activity, or at most would cause slight discomfort for a day. Dr. C. W. Hutt stated that immunisation against diphtheria had been done at a maternity and child welfare centre in Holborn since 1924. In Edinburgh immunisation was carried out in well-organised institutions, such as public elementary schools; administration was thus facilitated and the machinery for gaining the parents' consent was simple. It would be a great step forward if the London County Council authorise similar measures, for the method would then become favourably known to parents, and they would bring an increasing number of young children to the welfare centres.

Dr. C. S. Thomson communicated a paper dealing with the persuasion of the public. The administrative official, he said, must be a whole-hearted enthusiast—"a tearer if not a raging propagandist"—and the man who performed the actual tests and inoculation must be a lover of children and kindly disposed. In Deptford he had written articles and reports on the subject for his public health committee, had distributed numerous leaflets in the district, and had organised a meeting at the town hall, for teachers, parents, and councillors, where the Mutual Property Insurance Company's film, "The Risk of Diphtheria Banished," had been shown. When a child received its first inoculation he was careful to give the parents a form showing that protection did not take effect for six or eight months after the third and last injection. Parents ought to watch the tests and immunisation to see how simple they were, which is the best propaganda could be done by interviewing parents whose children had contracted the disease.

Dr. C. T. Maitland described his recent experience in Stoke Newington, where he had had more applicants for immunisation than he could deal with in the time available for this work.

An Address

ON THE

PRESENT POSITION OF THE VOLUNTARY HOSPITALS.

A Paper read before St. Mary's Hospital Medical Society on Oct. 19th, 1927,

BY E. GRAHAM LITTLE, M.D., F.R.C.P. LOND., M.P.,

DERMATOLOGICAL PHYSICIAN TO ST. MARY'S HOSPITAL.

SINCE I gave this title for a paper to your Society the early part of the summer much has been ritten upon the subject, and a strong general interest as been aroused anew in this question. I have been rther stimulated by a recent attack upon the luntary hospitals by Prof. Hey Groves, of Bristol, th which I shall deal later.

REPORTS OF PARLIAMENTARY COMMITTEES.

During the past few years Parliament has taken strong interest in the position of the voluntary spitals, and two Parliamentary bodies have tually investigated and reported upon that position. e first was the Voluntary Hospitals Committee, pointed on Jan. 25th, 1921, by Dr. Addison, when was Minister of Health, "to consider the present ancial position of voluntary hospitals and to make commendations as to any action which should be ken to assist them." That Committee issued an erim report in March, 1921, which dealt mainly th one suggestion. The Committee was very viously influenced by the knowledge that the luation of approved societies under the National alth Insurance Acts showed an enormous accu- ulated surplus over the amounts required for the rposes of the Acts. The Committee were "strongly the opinion that in the interests both of the hospitals d of these societies a substantial part of the posable surplus should be applied to providing a atribution towards the cost of maintenance of mbers in hospitals." These friendly societies have ilt up their accumulated funds very largely by the interested help of medical men, the health benefits ving been secured in great measure by the watchful e exercised by the medical officers to these societies, l there is widespread feeling that some of this umulated wealth should return indirectly to the erests served by doctors. The payments to hospitals patients, initiated in this way, have been greatly ended, a subject upon which I shall have something say later.

The Committee made a final report in May, 1921, first recommendation being that a central body uld be set up for Great Britain on the lines of the iversity Grants Committee, which should bear the me of the "Voluntary Hospitals Commission," der the Ministry of Health. Inasmuch as there s already an existent organisation for London in the ng Edward's Hospital Fund, the Hospitals Com- sion dealt only with institutions outside London. t Commission is still in existence. Another novation of far-reaching importance has come about he result of the recommendations of the Voluntary spitals Committee in 1921—namely, the setting up ocal committees outside London, in each county, nty borough, or other selected area. These local mittees have been of singular service in stimulating eral interest in the hospitals in each area; the orts published by one of these local committees, t for the city of Manchester, may be regarded as model for all others to imitate. Indeed, the work hese committees throughout the country probably ounts in no small measure for the marvellous overy which the provincial hospitals have made ards financial stability, as I shall mention later. committee of 1921 took a large volume of evidence from experts in hospital management, both lay and medical. Their conclusions in favour of maintaining the voluntary system are set out, I think with admirable cogency, on p. 8 of the final report (Cmd. 1335).

Like the preceding Voluntary Hospitals Committee, the Voluntary Hospitals Commission in their turn expressed themselves in favour of the continuation of the voluntary system. They declared in 1923 that "the voluntary system possesses strong vitality," and that "its chances of permanent survival are increasingly hopeful." They emphasise the fact that "the whole object of the Commission is to maintain with all the means at their command the voluntary system intact" (p. 15, Interim Report, 1923). The Commission had the important duty of distributing amongst the hospitals the special Parliamentary grant of half a million sterling, distribution having been completed by March 31st, 1924. The necessities for this grant arose largely from special conditions; the after-effects of the war were imposing an intolerable strain upon the voluntary system, and the grants made by the Commission were intended to meet this exceptional strain. Since that date the financial position of the voluntary hospitals has steadily improved. The annual reports for 1923, 1924, and 1925, issued by the Joint Council of the Order of St. John and the British Red Cross Society, are compilations of the utmost value for forming an estimate of the hospitals dealt with. These are exclusive of the area covered by King Edward's Hospital Fund for London, the reports of which should be consulted independently. The position of the provincial voluntary hospitals detailed in the report for 1925 (issued in October, 1926, the last available) showed that more than 75 per cent. of the number examined, some 750, showed a credit balance in their maintenance account, and their invested funds had increased by a sum of six million sterling in the financial period 1920–25. This achievement is notwithstanding the fact that there was an increase in 1925 over 1924 of 40,000 in-patients and 150,000 out-patients. "This wonderful record," says Sir Arthur Stanley, the Chairman of the Joint Council, "shows the great increase of confidence on the part of the general public in the treatment they receive when they enter the hospitals." The position in the provinces is rather better than that in London, 59 per cent. only of London hospitals showing a surplus for the year of general fund income over general fund expenditure. It is interesting to note, further, that the hospitals with medical schools attached (and there are 14 such provincial hospitals) show a very slightly larger cost than the hospitals without such schools, the principal difference being caused by the larger salaries and wages paid at the medical school hospitals. Those who wish to investigate these very interesting figures in detail are referred to p. 49 of the report of the Voluntary Hospitals Commission for 1925. The examination of a few items shows how closely expenditure has been regulated:—

	Medical school hospitals.	Non-medical school hospitals.
Provisions..	35·5	35·1
Surgery and dispensary..	29·9	23·2
Domestic	31·1	29·2
Salaries and wages ..	64·0	57·8

Perhaps some detailed figures will best convey the exact position at present. The average cost of a bed in 1913 was £100 a year; the average cost in 1925 was £200 a year. This present cost is met as follows: £36 from patients, £12 from public authorities, £59 from interest, dividends, &c.; the balance, constituting nearly half of the cost, is derived from voluntary gifts.

For the London area the authority which discharges the same functions as the Voluntary Hospitals Commission in the provinces is the King Edward's Hospital Fund for London, whose headquarters are 7, Walbrook, E.C. 4. This was founded in 1897 as a memorial of the sixtieth anniversary of the Queen's reign, Prince

Albert Edward of Wales being the President. It is now consequently celebrating its thirtieth anniversary, and a splendid meeting was held on Oct. 18th, 1927, of the King's Fund in combination with the League of Mercy, at which the Prince of Wales made a notable speech, rightly insisting upon the importance of propaganda in making the needs and the services of the hospitals as widely known as possible. He was able to announce that the sum distributed last year to the hospitals was nearly £40,000 more than the year before, and that gifts amounting to £25,000 had been received to celebrate the thirtieth anniversary. The purpose and activities of the Fund are thus set out; it does not assist at present in the foundation of new institutions except in cases where new populations have grown up since the date of the foundation of the Fund, nor does it entertain applications from institutions which have not been in existence in a properly constituted form for a period of at least three years. Its operations are confined to hospitals within 11 miles of St. Paul's. It has distributed since its foundation over five and a half million sterling. Its annual revenue for disposition at its discretion amounts to about a quarter of a million. During 1925, the last year under review, nearly three-quarters of a million was subscribed for building schemes as apart from maintenance. As is so fortunately the case with everything to do with the voluntary hospitals system, the administration of the Fund has attracted some of the best men in the profession to its service. The Fund has exerted the most beneficial effect upon all the activities of the London hospitals. Under the presidency of the Prince of Wales it is ever increasing its usefulness. The following is an extract from the speech which he made in July, 1924. He said :—

"I wonder if there is anyone who still thinks the voluntary hospital system is dead, or dying. If so, let him look at the facts and figures before us to-day. Even in 1920, when the crisis was at its worst, the hospitals of London had an income of £2,400,000, as against £1,500,000 before the war. Since 1920 their income has increased to £2,850,000 without counting any of the £400,000 raised by the Combined Appeal; £990,000 has been added to their endowments; and £1,100,000 has been received for extensions and improvements. This means that, over and above their annual income, which last year was nearly twice what it was before the war, the voluntary hospitals, in London alone, have received in three years two and a half millions for special purposes. And this does not include the additions, during this same period, to the investments of the King's Fund itself. Then, again, there are 1600 more beds than there were before the war, and the extension schemes now in hand, or proposed, would add another 1000. This is not decay or death; it is life—and very vigorous life. More than that, it is growth. The hospitals are not satisfied with merely making both ends meet—difficult as that seemed a short while ago. They are constantly expanding in response to the ever-growing need for better equipment and more beds. . . . Income of all kinds, voluntary contributions, patients' payments, and workmen's collections, the ordinary distribution of the King's Fund, all are increasing."

He was able to speak of two legacies which had increased the income of the Fund by £40,000 a year, and of still another legacy amounting to £200,000, which could be applied at the absolute discretion of the Fund. In 1926, again, the Prince was able to report that during that year some 1200 additional beds had been provided, 144 of which were earmarked for accident cases, a provision which represents an attempt to cope with the modern scourge of injuries from motor traffic. "This favourable position," the *Times* remarked in a leading article commenting upon this speech, "however, can remain favourable only if the generosity of the public keeps pace with the zeal of physicians, surgeons and nurses, research workers, and administrators."

The expenditure for 1925 of 143 hospitals, representing roughly 12,000 occupied beds, was somewhat more than three million sterling; the amount distributed by King Edward's Fund in the same year was just a quarter of a million. It will be interesting to read the report for the past year, which should appear in the press this week.

NEW SCHEMES.

The wise foresight of the administrators of the Fund is further exemplified by two new schemes which are under consideration at the present time.

1. A pension scheme for nurses and hospital officers has made great headway already, and has been adopted by 86 hospitals out of 143.

2. A still more recent proposition has to do with the provision of paying beds at the hospitals, and a committee presided over by Lord Hambledon, with Sir John Bradford and our senior surgeon, Mr. Warren Low as his medical colleagues, is thrashing out this matter.

One very beneficent reform instituted by the Fund was the scheme for a uniform system of hospital accounts. This scheme, established about four years ago, has been several times revised to meet changing conditions, and its acceptance is a condition of grant from the King's Fund, from the Sunday Fund, and the Saturday Fund, as well as by the Hospital Commission which deals with the provincial hospitals. By its experienced and sympathetic supervision economy in the management of hospitals has been encouraged more especially through the publication by the King's Fund of an annual statistical report showing the cost of working at different hospitals, and it is pleasant to note that our own hospital is one of the most economically conducted of the group.

Not the least of the services of the Fund has been its function in arousing interest in the hospitals amongst the working-class population through the establishment of the Hospital Saving Association which in its last report, 1926, showed an income of £150,000 a year. What is of even more importance than the money subscribed is the intimate affection awakened in the hospital-patient class by a wider knowledge of hospital problems looked at from their own point of view. The affection with which the class most helped by the hospitals regards the voluntary system was singularly demonstrated in the course of an appeal conducted in 1922 on behalf of the voluntary hospitals by the Educational Auxiliary Committee. Delegates were appointed from various educational bodies to serve upon this committee, and I was the representative of London University and had the good fortune to be appointed chairman of the Teaching Hospitals Subcommittee of that appeal. It was a poignant satisfaction to me as a hospital physician to note during the course of these investigations how deeply based was the confidence in the hospitals among all classes of the community, and very especially amongst the poorest of our people. If the poor could have their way there is little doubt indeed of the survival of the voluntary system.

The voluntary hospital is built upon humanity and the human interest is what keeps it the fresh and lovely thing it is. All of its component elements give of their best, freely and without reward. A great Admiralty lawyer, whom I knew well, found time from his busy practice to spend not less than two afternoons a week in the service of the hospital upon the board of which he was a member. The keynote of the whole system is voluntary service, which becomes a passion to those who give it. That evasive thing atmosphere emanates from these individual acts; medical staff, nurses, lay workers, students, all become imbued with the same ideal. An esprit de corps crystallises out which breeds an intense patriotism narrow if you like, but very potent for good. Let me give you an instance. A medical school just failed to become inscribed as a unit school, and was left consequently without the Government grant accorded to unit schools. The medical staff met this position with true British resourcefulness. They doubled their service to the hospital, they formed a unit conducted without pay. They had their reward in a school so flourishing as to compete quite successfully with the unit schools. Naturally such an effort demanded

sacrifice, and the most brilliant member of the staff, it was currently known, died from overwork at a comparatively early age. Would such an effort have been forthcoming under the ægis of a Government department? I think not.

The teaching hospitals are the flower of the whole voluntary-hospital system of this country, and the second great purpose served by hospitals, the education of students and nurses, would certainly suffer an unhappy change under State-aided control. They have for the past 200 years attracted to their medical service the ablest men and women in the profession. By the character of these workers and not by the surroundings in which they work, the teaching hospitals have become the great outposts of scientific advances in medicine and surgery, which within the present generation of men have so largely transformed the lives of all of us.

LISTER'S EXAMPLE.

A few months ago celebrations, world-wide in their extent, marked the centenary anniversary of the birth of Joseph Lister. Those of us who are old enough to remember, however faintly, the conditions which prevailed in our hospitals, even the most advanced of them, before the epoch-making discovery of Lister, can best gauge the beneficent revolution which he effected. Lister received his early training in London schools of medicine and ended his long and honoured life as a member of the staff of one of them. To-day, if there is no genius comparable to Lister, and where indeed can we hope to find his equal, there is a thousandfold greater army of research workers than was possible in his day. New methods of science have received an immense stimulus from his invention and from his example, and have provided far more precise means of investigation than ever before, in which our teaching hospitals have throughout taken the leading part, so that nowadays we have progressed far beyond the conceptions which prevailed at the end of the 19th century, when the medical schools were looked upon as little more than incumbrances to the hospitals and when voluntary subscriptions were often jealously safeguarded from any possibility of being used in the promotion of medical teaching or research. Besides acting as an ever-open asylum for the sick poor, the teaching hospitals have thus become the greatest schools in the world for the advancement of medical science.

The estimation in which the teaching hospital is held is, in fact, best demonstrated by the ambition and desire of the Poor-law infirmaries to imitate it as closely as possible, and their highest pride is to become affiliated to one or other of the voluntary institutions. We at St. Mary's have been fortunate in coming to a working arrangement with the Paddington Infirmary, with mutual benefit to both institutions. The fusion of these two distinct services, the Poor-law infirmary and the teaching hospital into one whole, would, I feel certain, be a retrograde step, for their objects are different; but it is, on the other hand, an unfortunate fact that the infirmaries have not been sufficiently made use of for the purpose of teaching, and an extension of the experiment which we have tried at St. Mary's of a loosely knit connexion between hospital and infirmary should be widely repeated.

INCREASING DEMAND ON THE VOLUNTARY HOSPITALS.

The very excellence of the treatment now obtainable in voluntary hospitals has been to some extent their own undoing; the waiting-lists for admission to these institutions are getting ever larger, whereas numerous beds are permanently empty at the Poor-law hospitals. A class is clamouring for treatment in voluntary hospitals which was never willing previously to consider such treatment as a possibility, and the necessity to meet the demands of the middle class for hospital service has become very insistent. Our own hospital, with its ready adaptation to calls upon it, is considering very carefully the problem of providing paying beds. There are two views held as to the propriety of setting apart part of the accommodation at voluntary hospitals founded for the relief of the sick poor for the reception of patients who cannot wholly deserve this appellation. The experiment has been in operation for some years at some other hospitals.

THE MIDDLE CLASSES AND MEDICAL TREATMENT.

It has always been something of an anomaly that the best medical attention in this country under present conditions can be obtained only by two classes, the rich and the poor, and both classes are attended by practically the same medical advisers. A member of the staff of a great hospital practically divides his day between these two classes; half of his time will be spent in tending the sick poor, for which he gets paid nothing, and the other half in gleaning from the rich the means which enable him to devote himself to his profession and at the same time to succour the poor without fee. But the middle class remains outside of this system altogether. The conditions of modern medicine, which necessarily entail team work—that is to say, the examination of the patient by numerous specialists—deprive the middle-class patient, as a rule, of the full benefits of proper examination, and consequently of proper treatment. Upon the middle class lies nearly the whole financial burden of our country, and it is, in my opinion, high time that some provision was made for their proper medical treatment. The rich have perhaps not fully recognised the part which the voluntary hospitals in reality play in providing themselves with the first-rate medical advisers which their money can command, for these advisers win their experience and their skill by their work at the voluntary hospitals. A wider extension of hospital propaganda would probably secure consideration from this class which is best able to give. What can be done by generous donations may be exemplified in the splendid Wells bequest, administered by the King's Fund, which was almost wholly responsible for the additional 1200 beds to which I have drawn attention. It might perhaps be usefully pointed out to wealthy donors that the Chancellor of the Exchequer, incredible as it may sound, actually makes a concession to hospital subscribers who promise an annual donation for at least seven years; the amount of these subscriptions may be deducted from income-tax returns and, perhaps a still more important fact, from the super tax which is so especially aimed at the very rich.

Indeed, propaganda is one of the most urgent necessities of the position, and if praiseworthy needs are explained to the public, the public quite astonishingly generously responds. Our own hospital has obtained by an appeal privately conducted the large sum of £40,000 within a few months, and the cost of collecting this very considerable amount has been less than 2*d.* in the £. St. Bartholomew's Hospital is building a great new surgical block, money for which appears to be forthcoming without difficulty. Under the voluntary system the expenditure of the money received is probably more economical and more sensibly guided than under any other system. Again, the spur of competition in wise management comes into play, and donors may be completely confident that the money they give will be spent in the very best possible way for the relief of suffering, the promotion of medical science, and the immense amelioration of the health and comfort of the whole country.

BUREAUCRATIC IDEALS.

In a State so impoverished as ours at the present time the purposes for which money is used become of primary importance. The bureaucrat spending other people's money is proverbially lavish; too often he is obsessed with megalomania, and bricks and mortar are his fetish. Prof. Hey Groves, who seems imbued with bureaucratic ideals, clamours for "hospitals of a thousand beds," supported by the rates, but money spent upon buildings must be subtracted from money spent upon the more vital needs of the time, medical research and improved methods of treatment, and the value of a laboratory, to take a single example, is not necessarily dependent upon the magnificence of its

installation. Leonard Hill once made a very telling reply to a University administrator who was condemning a certain famous laboratory for its scanty accommodation and equipment. Helmholtz, he said, had made his epoch-creating discoveries in crystallisation by working out the conformation of crystals with models made with his own hands out of wires and corks. Here, as always, it is the spirit that counts and not the material with which that spirit works. It is better to have A1 workers in C3 laboratories than C3 workers in A1 laboratories; the man is more important than the aids which he uses. Public departments are apt to pamper the official and to starve the scientific worker. In Budapest, which I visited in 1913, the medical clinics were entirely financed by the Government. I saw a magnificent building provided for the dermatological department; but the scientific workers in it were receiving salaries which could only be described as pitiable—e.g., the chef-de-service, a first-class medical histologist, after 18 years' service was getting less than £200 a year. One of the first results, therefore, of change of control of the hospitals would be to magnify out of all proportion the material as against the man, and inasmuch as there is no large margin of money available, real research would inevitably be sacrificed to the provision of bricks and mortar and the multiplication of paid Government officials.

It is to be borne in mind by all concerned that the alternative to the voluntary system is exactly this bureaucratic control which would necessarily be many times more expensive. Prof. Hey Groves shares the innocent delusion of the Socialist in our midst, that "somebody else" would always supply the money. He writes: "If the profession stood four-square and told the country that our voluntary hospital system was essentially bad, then the money would be forthcoming just as readily as it was for education or the National Insurance scheme." He forgets, however, to ask who pays for these expensive provisions. The "country" is nothing but the ratepayers—i.e., "ourselves of the middle classes"—and a further addition to the crushing rates now almost entirely borne by those classes might quite conceivably bring our whole body politic crashing down. Mr. Brock, the Secretary of the Voluntary Hospitals Commission, acutely points out that nearly the whole burden of the voluntary hospitals is borne by the middle classes, those classes who have the least direct benefit from the hospitals, and that a subtle change has been overtaking us in that, with the immense extension of insurance benefits that every political party has practised within the last few years, the "necessitous poor" have been largely eliminated; the burden of that elimination again has been mainly borne by the middle classes, but there are not wanting signs that those "patient oxen" are reaching the end of their tolerance of these conditions.

PAYING BEDS.

The provision of paying beds at the hospitals serves a twofold purpose. (1) It goes some way towards meeting the changed condition of the middle classes who are taxed almost out of existence and who alone of our community do not in fact obtain the best medical aid although they are the chief means of providing it for others. For the average middle-class man a major operation for an acute illness is a financial disaster from which it may take him years to recover. Nowadays it is expensive to be born and often not less expensive to die, but a prolonged recovery is more costly still. These conditions have come about from the change in medical practice; it is no longer possible for one man to deal faithfully with any but the simplest medical cases, and the provision of many experts is necessarily expensive. (2) It is not proposed to make a profit out of these beds, but they do pay all expenses, both of building and of medical service. If and when the voluntary contributions to a hospital allow of its doing so, these beds could revert to the poorer classes again and new provision be made for paying beds if the need should still exist.

While it is true, as the objectors to the voluntar system emphasise, that the hospitals are now solver partly because contributions are asked for from near all who use them except the very poor, it must b remembered that the control of the hospitals rests wit the voluntary staff. Under the State-controlle system conditions would be entirely different, and th management would pass into the hands of bureaucrat officials who would be tied up in regulations and re tape, and would not have the knowledge to deal wit the problems of sickness that the present admini trators so abundantly possess.

THE HOSPITALS AND MEDICAL EDUCATION.

I must dwell a little more upon the aspect which of most direct interest perhaps to the present audienc —namely, the part played by the teaching hospita in medical education, both of doctors and nurses. L us take the last point first. In my student days th sisters and nurses were largely drawn from the upp domestic-servant class. They were often very worth women for routine work, but their lack of educatio and intelligence hampered the doctor at every turn We owe it to the voluntary hospitals that Sarey Gam has been finally dispossessed by Florence Nightingale

The part played by the hospitals in advancin medical knowledge is little appreciated by the publi Any medical discovery made by a medical man regarded as a matter of course. The epoch-makin inventions of anæsthesia and of antiseptic surger which had their origin at teaching hospitals, hav changed the whole face of medicine and of surgery one generation. These discoveries stand out, bu there is an enormous imperceptible movement forward of medical knowledge as the result of the experience doctors working in the hospitals, and the benefit that experience is shared with all the world. Th voluntary system is practically peculiar to th country. It suits the genius of our people, which always individualistic, far better than the Stat controlled institution. Under the voluntary syste our medical schools, because they have attracted th best brains in the profession, have become the mo famous centres of medical education that the wor knows, and more especially in the practical art medicine in which Englishmen have taken the leadin place since the time of Sydenham. Under our syste of teaching the British general medical practitioner easily the best trained in the world, as the war ver clearly demonstrated. The acid test of efficiency readiness of adaptation. "Our surgeons," sa MacPhail, "performed the most delicate and profoun surgery in field ambulances and casualty clearin stations, upon trestles in huts or open tents, with on the heat from a brazier and not even running water They were able to bend their means to their nee because they were trained by direct contact wit actuality in the admirable British way which learned in hospital schools.

Side by side with this ancient institution of volu tary hospitals—and the oldest voluntary hospita are over 800 years old—there has grown up wi increasing frequency in later years another set institutions, the Poor-law hospitals, formerly infi maries, whose resources are derived from the rates, an much searching of heart is obvious in the medic profession at the present time as to the ultimate fa of the voluntary hospitals in competition with the rate-aided institutions. At the present time th Poor-law hospitals are under the management Boards of Guardians. Mr. Neville Chamberla proposes some time next session to bring befo Parliament a measure which will transfer the contr of these hospitals to local municipal authorities; in th case of London to the London County Council.

STATE-CONTROLLED HOSPITALS.

This is a very bureaucratic age, and the encroac ments of bureaucracy upon all our institutions h never been more insistent or menacing. The voluntar hospitals shine out as some of the last great foundatio to remain essentially untrammelled by State inte

rence. Are they destined in their turn to yield to at ever overwhelming tide of State control, and ould they better serve the needs they exist to satisfy they ceased to be voluntary and became subject to overnment or municipal control? It must be membered that the Poor-law infirmaries have been existence for very many years and have not been nspicuously successful in winning the affection of e patients treated nor in the advancement of medical ience. Those of us who had experience of State-ntrolled hospitals during the war were, I think, pressed by the absence of elasticity and initiative those institutions. When the War Office wanted 0 wounded soldiers to be suddenly admitted to spital in a grave emergency they appealed not to eir own State hospitals, but to the voluntary London spital, which, because of the resilience resulting m voluntary management, was able within hours to convert 300 of its beds for military rposes. Prof. Hey Groves has made himself the ampion of the State-aided and State-controlled spital. He was obviously entirely unaware of the ual position of the voluntary hospitals as regards eir present financial and moral stability, for he clared "the system is not dead, but moribund, and i laboured life is kept going by stimulants and ificial respiration." This premiss, upon which he ses his attack, I think has been demonstrated to be sound by the figures I have given.

Prof. Hey Groves, like many other persons in ts age, seems to be obsessed by the material as posed to the spiritual, forgetful of the old Greek age that the strength of a city lies in its men, in its walls. He ascribes to what the Americans turesquely call "plant" more importance appa-rtly than to the quality of teaching. There is a shing attack upon what one might call this American ception by Sir Andrew MacPhail.[1] Dealing with erican methods of medical education he says: "To Americans a school too often means buildings, uipment and machinery . . . To English teachers, d in the tradition of our great voluntary hospitals, medical school derives its virtue from the quality the human beings who teach or learn in the school." e difference of outlook is cardinal. It is a matter of dition and sentiment, about which there is no ument. This dependence upon external adventi-is aids has been satirised by MacPhail as an lication of the American method in business, ch he sums up as "uniformity, single standard, ss production; what may be called the mechanical hod." "Under this system," he says, "the surgeon ws the patient merely as an arrangement of type-tten cards, he sees him for the first time uncon-ous upon the table, when he comes, like a masked ecutioner, to complete the sentence of the judge." Canadian surgeon whom I met on a voyage some rs ago gave me a mirthful description of an erience he had had in an American operating-tre. He told me that he had been taken into the e-room by the operator, where all the participators e stripped to the skin, scrubbed all over with nail-shes and soap, then clothed in sterilised pyjamas, the cohort thus prepared waded barefoot into the tre in a sea of antiseptics. The Canadian surgeon, nconsiderable authority himself, took the trouble xamine the statistics of the American operator as pared with his own, which were in the same field ractice, and was comforted to find that his own res compared extremely favourably with those of olleague.

rof. Hey Groves attempts to support his ment for what one may call the municipalisa- of the voluntary hospitals upon the advantages laims for the control of education by the State. seems to me that this parallel is singularly rtunate for his thesis. There is a wide-ad present uneasiness as to the results of this icular experiment in education, the expense which has become a most formidable and ever-augmenting strain upon our community, and the results of which are by no means commensurate with the fantastic cost. It so happens that within the last few days a convincing object-lesson has been furnished of the disastrous results upon secondary school education of the extension of municipal or depart-mental control of schools. A public school in Sheffield, King Edward VII. School, found itself in difficulties with the Sheffield City Council which had been captured a short time previously by the Labour Party, who used their majority to dissolve the independent governing body of the school and to place it under the control of the "Secondary School Sectional Sub-Committee," that is to say, under municipal control. The immediate result was that the Headmasters' Conference removed the school from its list of accredited public schools, and the headmaster himself, a man of great distinction, resigned his appointment. The headmaster of Harrow, commenting upon this incident, makes some observations very pertinent to my present thesis. "Schools," he says, "are living things; they are not machine-made, mass-produced shops for the sale of instruction." "Every great school is the expression of human personalities, whose work cannot be fruitful to the utmost unless it is devoted to the service of a school whose individuality is felt to be both real and free to develop on lines not necessarily prescribed. But this sense of individuality is lost when a school becomes one of a mass, all nominally responsible to an education committee of changing membership, which is itself largely in the hands of its director."

The estimation in which State-aided education is actually held may be best gauged by the individual man's actions. As soon as a man in any walk of life is able to afford it he sends his children to be educated, not at the council (State-aided) schools, but at the public (voluntary) schools.

CONCLUSION.

I would sum up the position, therefore, in the following way:—

1. The voluntary hospitals have actually turned the corner of their fate and are more solvent at the present moment than they have ever been in recent history.

2. The voluntary hospitals have won the affection and confidence of the whole community in a way which would not be likely to be achieved by any other institution.

3. In their advancement of medical science the voluntary hospitals have immeasurably outdistanced Poor-law infirmaries who have been their competitors for a sufficiently long time to allow of conclusions being drawn from that competition.

4. The voluntary hospitals command a tradition of service which cannot be imitated by any institutions lacking their long organic growth.

5. The administration of the voluntary system is incomparably cheaper, because it is voluntary, than any State-controlled system could be. Moreover, the purposes to which money under State control would be applied would probably not be the same as those upon which voluntary hospitals are concentrated. They would be inferior purposes in every case, and the waste of money consequently would be even more disastrous than the actual expenditure would indicate.

6. The voluntary hospitals are the growth of centuries, moulded to their uses in each generation, and representing the sturdiest of English characteristics, that of self-help; while State institutions are the product of a weak-kneed generation, ever more and more dependent upon that nebulous abstraction, the State, a dependence which unhappily so often means in practice the glorification of the art of sponging, as witnessed by that most formidable incubus of modern days, the unemployed dole.

These are the propositions to which I invite your assent and, if I win it, your resolve that you will help by every means in your power to maintain the voluntary hospitals, to which you all owe so much.

An Address
ON
INSOMNIA.

Delivered before the Medical Society of London on Dec. 12th, 1927,

BY EUSTACE M. CALLENDER, C.B.E.,
M.D. BRUX., M.R.C.S. ENG.,
EX-PRESIDENT OF THE SOCIETY; MEDICAL OFFICER, ST. AGATHA'S HOME, ST. JOHN'S WOOD.

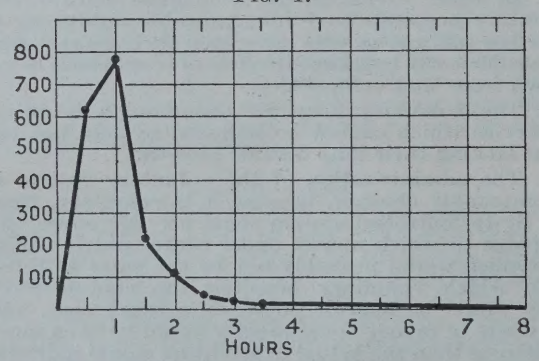
SLEEP has been defined as "a period of rest for the body and mind, during which volition and consciousness are in partial or complete abeyance and bodily functions partially suspended." (Dorland.) One writer speaks of sleep as a habit, another says it is a function of the whole brain if not of the whole body. (Wechsler.)

Some physiologists say that sleep is more necessary than food, that "a man can fast for four or five weeks, but if forced to do without sleep he will die in a few days." (Lyle and De Souza.) But Dana says, "Man can exist without sleep for about the same time that he can do without food—viz., three or four weeks—but he cannot live without it." Experiments by Piéron showed that young dogs deprived of sleep died in from four to six days, but Kleitman, of Chicago, and his colleagues deprived themselves of sleep for periods of from 40 to 115 hours, and with the exception of intense drowsiness, remained remarkably normal. During these periods the blood, urine, and fæces were examined, the heart, pulse, blood pressure, respiration, appetite, digestion, basal metabolism, and reflexes were all observed, "and," says Halliburton, "any departures from the normal, if present at all, were trivial."

NORMAL SLEEP AND ITS POSSIBLE CAUSES.

In normal sleep the most striking and important fact is the partial or complete loss of consciousness, due undoubtedly to the lessened activity of the brain tissue and particularly of the cortex cerebri. The power to make conscious movements is first lost, and the use of the special senses disappears. The first of these to go is vision, the last hearing. During

FIG. 1.

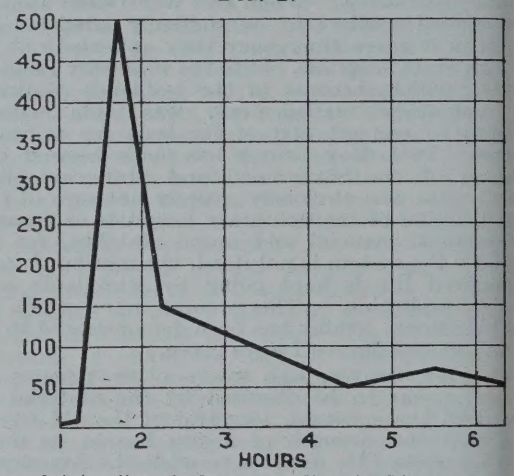


Curve illustrating the strength of an auditory stimulus (a ball falling from a height) necessary to awaken a sleeping person. The tests were made at half-hour intervals, and the curve shows that the distance through which it was necessary to drop the ball increased during the first hour, and then diminished, at first very rapidly, then slowly. (Modified from Howell's "Text-book of Physiology," tenth edition, p. 262. Published by W. B. Saunders Company.)

sleep hearing is the most easily excited sense, the sense of touch is more difficult to arouse, and taste and smell still more difficult. All voluntary muscles are relaxed. Respiration becomes deeper and slower and tends to rise and fall as in Cheyne-Stokes respiration. The secretion of urine, tears, and mucus are all diminished. When the sleepy child rubs its eyes it does so because the secretion of tears is becoming less and making its eyes feel gritty. Pulse frequen is lessened, blood pressure falls, the knee-jerks a entirely lost, and the Babinski sign becomes positi All these point to inactivity of the cerebral cortex.

A very important point in normal sleep is t variation in its intensity. This has been investigat by many observers, Kohlschütter, Czerny, How and Michelson, to mention a few. Their investig tions were made by finding, at regular interv during sleep, the intensity of auditory stimuli requir to cause waking. It was found that there was

FIG. 2.



Curve of intensity of sleep according to Mönninghoff a Piesbergen. The figures along the ordinate show the relat intensity of sleep, measured in milligramme-millimetr expressing the intensity of the sound, caused by a falli body, necessary to awaken the sleeper. (Modified fr Howell's "Text-book of Physiology," p. 264.)

rapid increase in the intensity of sleep during t first two hours of slumber, which reached its highe point between the first and second hours, and th dropped very rapidly again, so that by the third ho the sleeper was very near the margin of consciou ness. From that point onwards the depth of sle gradually became less until waking occurred. Th is well shown graphically in Kohlschütter's cha (Fig. 1). Mönninghoff and Piesbergen, in simil experiments, observed a second rise in the intensi of sleep during the sixth hour (Fig. 2), and Czer shows a very much greater rise from the seventh the eleventh hours in a child of 3 years old.

Many physiological explanations or theories of t cause or causes of sleep have been put forwar Preyer and Obersteiner attribute sleep to fatigue the brain cells, caused by the accumulation of ac waste-products in the blood. Pflüger suggests th it is due to gradual consumption, during the waki hours, of the intramolecular oxygen in the brain cel whilst Duval, Cajal, and others suppose that t cortical cells are cut off from incoming impulses contraction of their dendrons.

A number of writers attribute sleep to the form tion of a special toxin, which accumulates in t blood during waking hours, and finally inhibits t activity of the cortical cells. There are also t inhibitory theories of Pavlov and Shephard. T floor of the third ventricle, the aqueduct of Sylviu and the pineal gland have all been considered playing an important part in the production of slee But the one important fact would appear to be t cerebral anæmia which exists during sleep. Howe Mosso, and others have demonstrated by plethysm graphic observations that in sleep the volume of t limbs is increased. Arterial pressure is known fall, and Hooker has shown that venous pressure al falls, and that a venous pulse may be observed the hand, indicating a dilatation of the cutaneo arteries. More blood, then, is circulating in t limbs than during the waking state, and the volun of blood remaining the same there must be less blo

in the brain, and observations of the brain itself through a trephine wound have shown that its volume is decreased during sleep. Sachs and Hausman, in their book on "Nervous and Mental Disorders," say, "It is generally admitted that a very important factor is the cerebral anæmia during sleep. As soon as we go beyond these facts we are indulging in pure speculation."

INTERFERENCE WITH SLEEP.

The periodical recurrence of sleep would appear to be due to fatigue of, and therefore lessened activity of, the vaso-motor centre in the medulla brought about by its continuous activity during the waking hours. If we bear in mind the important phenomena of sleep to which I have drawn attention, the nice adjustment of the circulation, the fall in blood pressure, the dilatation of cutaneous blood-vessels, the slowing of the heart and respiration, the rapid rise, and also the equally rapid fall in the intensity of sleep, and the varying degree of loss of the special senses, we can, I think, form a useful idea of the causes of some of the varieties of insomnia and perhaps of their rational treatment. Some of these experiments also, I think, tend to show that insomnia in a healthy adult produces less serious results than insomnia in the young.

Anything which upsets the nice readjustment of blood distribution may give rise to insomnia. Anything which maintains the activity of that most easily aroused special sense—hearing—or the next most easily activated—touch—also anything which keeps up mental, and therefore cerebral, activity, for this demands adequate blood-supply to the brain, will tend to cause sleeplessness. And so it is easy to understand that insomnia will arise in states of excitement, worry, anxiety or emotion of any kind, in pain, in fever, in cases of heart disease, respiratory disease, and in cases showing extremes of arterial pressure from whatever cause. We have many of us no doubt experienced the insomnia which is brought about by a sudden change in atmospheric pressure when rapidly ascending to a considerable altitude, and again on descending to a much lower level. I can well remember going up to the snow-line from Montreux in one day and being completely sleepless that night, and again being equally sleepless when descending again to Geneva.

The indifferent night's sleep obtained on the first night in a strange bed is due, I think, largely to unaccustomed touch sensations conveyed by the bed and bedding.

NOISE AND CONSCIOUSNESS.

A very common complaint nowadays is, "I go to sleep whenever I get into bed and sleep soundly for two or three hours, then I wake up and cannot get to sleep again until the early morning." (I think the writer of the Book of Proverbs must have suffered thus when he wrote, "He that blesseth his friend with a loud voice, rising early in the morning, it shall be counted a curse to him."—Prov. xxvii. 14.) In the almost ceaseless noise of a great city like London this waking after some two hours of sound sleep is not remarkable. Those of us who, not infrequently, have to be at work during the night know that the noise of traffic does not die down, for I think it never ceases entirely much before 3 o'clock in the morning. The person who goes to sleep, say, at 11 P.M. at 1 or 1.30 A.M. suffers from that drop in the intensity of sleep which is illustrated in Figs. 1 and 2, and is kept awake by the traffic until the noise is somewhat reduced and the second rise in the intensity of sleep is due.

Others complain that, to use a very expressive Scottish phrase, they "cannot catch their sleep" when they settle down in bed. These people lie awake for an hour or two after which they often fall very soundly asleep and so remain until "called" in the morning. I know a lady who goes to bed regularly at midnight and never falls asleep until 3 A.M., but from that hour until 8 A.M. she sleeps so soundly that this five hours of sleep is quite sufficient for her.

Then there are those who, sleeping for the first two or three hours wake and remain awake, failing to fall asleep again during the early morning, and, lastly, there are many who complain of sleep repeatedly disturbed by dreams. These are always or repeatedly near to the margin of consciousness, whose sleep is never sound and never restful.

Complete and entire absence of sleep is very rare excepting in acute illness, painful diseases, or those neuropathic and psychopathic conditions which will be dealt with by those who follow me to-night. Insomnia in any of these forms may arise in conditions of ill-health, trivial or serious, and its treatment is the treatment of this underlying cause. Those who, without any ascertainable ill-health, habitually wake after two or three hours' sleep and lie awake, I sometimes advise to go to bed an hour or two later and rise at a correspondingly later hour. In this way, and particularly if they live, as I do, on a main traffic route, their insomnia is overcome or avoided. For I have found for myself that it is little good my being in bed in London before midnight. The traffic invariably wakes me at about 2.45 A.M., but the decrease in its volume after that hour allows me to fall asleep again and sleep until morning. I seldom sleep throughout the entire night in London, but I seldom wake during the night in the quiet of the country.

SOME COMMON CAUSES OF SLEEPLESSNESS.

This waking in the middle of the night is common in the debilitated and the aged. It is common in those who take too little food, or who take their evening meal very early. It is common in those with very low blood pressure from whatever cause, as is also the inability to fall asleep in the first instance. An extreme example was that of a lady sent to me by the Society for the Relief of Necessitous Gentlewomen, to which I am physician. Owing to sheer poverty this patient's daily food allowance, proved upon inquiry, to be one cup of soup, two or three of tea, and a few slices of bread and margarine. Her chief complaint was that she slept for only two hours in the early part of the night. Her systolic blood pressure was 110. She showed no signs of disease, and her insomnia disappeared when she had been provided with adequate food.

An alteration in the hour at which the last meal is taken is sometimes important, and in the case of the aged and debilitated, some hot liquid food in the middle of the night, milk, or one of the patent foods, will often act as a soporific. In the case of patients with very low blood pressure who wake thus, I have not infrequently found that a cup of hot tea or coffee will enable them to sleep again, I suppose by raising the blood pressure. Any of these can easily be placed in a thermos flask at the bedside.

It is hardly necessary here to speak of many of the common causes of sleeplessness—the late supper or heavy dinner, too much alcohol or too much tobacco, the taking of coffee or tea in the evening, overwork or working until near bedtime, sleeping in a room which is too hot, badly ventilated, or too cold, lying with the head too low and perhaps in some cases too high, wearing too much clothing at night, being overburdened with bedclothes, or being too cold in bed. All precautions regarding these would appear to be matters of ordinary common sense, yet we are all so accustomed to find this quality lacking, even among educated persons, that it is necessary to pay particular attention to these details, and even to see that a suitable and proper type of bed is being used. For my own part, I prefer the box-spring type of bed to any other.

It is well never to accept a complaint of insomnia without very careful investigation. Only a few days ago a lady consulted me, complaining of complete loss of sleep. She affirmed repeatedly that she got no sleep at all, but under rather severe cross-examination she had to admit that she got five hours of sleep every night, and a middle-aged, valetudinarian gentleman, who made a similar statement, was found, when a nurse was employed to record his hours of slumber, to sleep regularly for 7½ hours.

SUGGESTIONS FOR TREATMENT.

The treatment of sleeplessness due to pain or painful conditions is so obviously the treatment of the cause of pain as to be outside the scope of this discussion, but I may perhaps be pardoned for referring to one or two remedies which may relieve pain and admit of sleep.

Many kinds of pain are relieved by a dose or two of aspirin. The pain in a carious tooth with an exposed pulp cavity is promptly relieved by the application of a little pure carbolic acid on a tiny pledget of wool, and even the misery of a dental abscess may be relieved sufficiently to permit of sleep by the application to the face of the old household remedy, a pepper plaster, made by soaking a piece of thick flannel in brandy, peppering it freely by means of the pepper-pot, and tying it on to the face—pepper to skin. It can be left on all night without fear of blistering or marking the skin. Pruritus ani and pruritus vulvæ can often be best relieved by the application of a conium ointment which, if necessary, can be prepared with double the quantity of succus conii in the Pharmacopœial ointment.

Insomnia occurring in patients with hyperpiesis, particularly in chronic renal disease, may be relieved by a good dose of calomel, which, as long ago pointed out by the late Sir William Broadbent, acts as an hypnotic long before it acts as a purgative. A hot bath immediately before going to bed will help some patients to sleep, chiefly those with too high blood pressure, and in those with very low blood pressure strychnine given two or three times a day is often of great service. The sleeplessness in advanced mitral disease with engorgement of the liver is often very much relieved by placing as many as a dozen leeches over the hepatic region. Leeching has gone very much out of fashion of late, which I think is a pity. In the dreadful headache and insomnia following severe cerebral concussion, nothing gives such relief as a couple of leeches on each temple or behind each ear.

HYPNOTICS.

So far I have made no mention of hypnotics because, I am sure, it will be agreed that we should avoid the use of these drugs in the treatment of insomnia if that be possible. But there are cases in which the sleeplessness itself is causing such havoc that these must be given. We must not let the patient die or go out of his mind whilst we are endeavouring to cure the disease causing his sleeplessness. Sometimes the original cause of the insomnia having been removed the condition remains as a sort of bad habit.

In my early days we had comparatively few hypnotic drugs to choose from. Now their name is legion, but I am not at all convinced that the newer remedies are the best. The bromides are, I think, invaluable, and combined with chloral hydrate form an excellent and safe sleeping-draught in a very great many cases. Insomnia is not common in children excepting in conditions of obvious illness which is its cause, but when it is necessary to give a child an hypnotic it is well to remember that they can take both bromide and chloral, even in early infancy, safely and with good effect. Again, one is often called upon to prescribe a sleeping-draught for wife or mother worn out and sleepless with long watching, nursing, anxiety, or sorrow. Nothing acts so well or so safely as bromide and chloral.

In the cases where the patient sleeps for two or three hours, then wakes and lies awake for hours, a dose of one of the bromides at bedtime on several successive nights will sometimes effect a cure. But often in these cases a dose of sulphonal at bedtime acts well. Sulphonal takes a long time to produce sleep. If the dose is timed properly it will produce its effect at about the time the patient would otherwise wake. If the insomnia of this type has become a bad habit, the cause having long since been removed, a dose of sulphonal, given thus on three successive nights, will not infrequently effect a permanent cure. Where a patient is long in going to sleep, sleeps for only a short time, then remains awake for hours, a combination of trional and sulphonal is often useful. The trional sends him to sleep and, later, the sulphonal keeps him asleep.

Veronal I am not very fond of. It has sometimes seemed to me to be more toxic than many of these barbituric acid derivatives, all of which I have found to be unduly so in patients suffering from a toxæmia of any kind, and particularly that occurring in or arising from renal disease.

Aspirin will often act as a producer of sleep, in my opinion probably by causing a dilatation of peripheral vessels. It is often of great value in the pain and discomfort following a surgical operation. It is safe; it can be given by the bowel. I do not know that it has any undesirable after-effects, and even if the patient does develop an aspirin habit it is not a very serious matter.

OPIUM.

But opium and its derivatives must remain for all time the great pain-killers, and in painful conditions the great sleep-producers. In proper cases they are invaluable. Morphia in one form or another, and in many cases combined with atropine, is the one safe hypnotic in serious heart disease, acute pneumonia, and, following the major surgical operations, severe injuries and shock.

There used to be a prejudice—I do not know whether it still exists—against the use of morphia for the dreadful insomnia of delirium tremens. But I am not sure that in delirium tremens hypnotics poured into a hopelessly disordered stomach in dose after dose do not lie unabsorbed until, with commencing recovery, they are all absorbed at once, poisoning the patient. Would not morphia given hypodermically be both safer and more effectual? Again, it used to be taught that it was not safe to give morphia and bromide together. Is this so? Is hyoscine a good remedy in delirium tremens? I have found it of the greatest service in some cases of insomnia, and it has this great advantage, that it can be administered without the patient knowing that any hypnotic has been given. The following is a typical case:—

> Shortly after the war a young war widow living in an hotel was robbed one night whilst at dinner of all the trinkets her late husband had given her, together with the personal belongings of his which had been sent to her from France after his death—his watch, his signet ring, and the rest. Already depressed and "nervy" she completely broke down, and was treated for some days by other women in the hotel, chiefly with stimulants and sympathy. After she had been under treatment in a nursing home for some time and was much better, she remained sleepless. In her last cup of hot milk at night, for several nights, was dissolved gr. 1/150 of hyoscine hydrobromide. Her insomnia was soon cured, and her confidence in herself restored, because she thought that her sleep was quite natural. For very long, after this nightly dose of hyoscine had been omitted, she continued to take her cup of milk, satisfied that it would send her to sleep.

It is a very great advantage, when hypnotics have to be administered, to be able to give them without the patient's knowledge, but this, as a rule, can only be accomplished in acute or serious illness and with the help of a tactful nurse. But I always make every endeavour not to give a patient a prescription for any of these remedies. I prefer to give him two or three tabloids, tell him when and how to take them, and to return next day and report the effect. The dose can then be repeated or not as desired.

I have said little or nothing about the more serious forms of insomnia. It is hardly necessary to remark that whenever complaint is made of insomnia—and especially when we meet with that condition of complete insomnia for which the Romans had the more expressive term, exsomnia—we must be very carefully on the look-out for serious disease. And finally I would say, when treating insomnia, it is always a mistake to give hypnotic drugs until there is no doubt that they are really required.

VACCINE TREATMENT OF IMPLANTED TUMOURS IN THE RAT.

SUBSEQUENT IMMUNITY.

BY THOMAS LUMSDEN, M.D. ABERD.

(From the Department of Experimental Pathology, Lister Institute, London.)

IN previous communications[1] the following facts have been reported: 1. Specific antisera can be produced which kill cancer cells cultured in vitro without damaging cultures of normal tissues. 2. When applied under specially favourable conditions to certain implanted tumours in the living animal, such antisera not only cause regression of the treated tumour, but of a coexisting untreated tumour as well. Animals so cured are immune to subsequent inoculations of the tumour concerned. 3. The mechanism of this immunity has been demonstrated to be due to the presence of antibodies in the serum of the immune animal. These, however, only become effective in the animal which produced them, when aided by some excretion from extravasated leucocytes. It may, therefore, be accepted that animals can acquire an immunity against tumours comparable in many ways to immunity against bacteria. Mere excision of a tumour does not evoke such immunity, nor does gross local destruction of a growth by powerful poisons. In the latter case destruction of the cells has apparently gone too far, so that not only their vitality but also their antigenic factors have been destroyed. Many attempts were made to attenuate tumour fragments by means of heat, cold, antiserum, ether, distilled water, and other agents in such a way that they should lose their infectivity while retaining their antigenic power. As previously reported, these attempts were almost always unsuccessful. It was found impossible to accomplish the appropriate degree of damage; either the fragments were insufficiently attenuated and gave rise to tumours when inoculated into animals, or the process of destruction was carried too far, the antigenic factor in the cells was destroyed, and no immunity was evoked. There was still a hope that (on the analogy of bacterial vaccines) if some reagent could be employed, the intensity of whose action could be graded so as just to kill the malignant cells, without at the same time altering them chemically so much as to do away with their antigenic properties, the injection of these cells might immunise an animal and perhaps even cause regression and cure of a growing tumour.

Formalin, which is used for a similar purpose in the preparation of bacterial vaccines, suggested itself as a suitable reagent for this purpose on account of the fact that it kills and fixes cells without altering greatly their chemical constitution. There was also the possibility that formalin might preserve the antigenic factor in the cells in such a way as to prevent it from altering seriously during the period which must elapse after inoculation into the body and before absorption into the blood takes place.

The present paper deals with the investigation of these possibilities.

Methods and Experimental Observations.

(*a*) *Attempts to produce immunity in normal rats by means of an emulsion of formalised tumour cells.*—Jensen's rat sarcoma (J.R.S.) was ground in an apparatus (broyeur Latapie) which reduces it to separate or small groups of cells without interfering with its infective power. This material was mixed with about ten times its bulk of 0·1 per cent. formalin, and was injected subcutaneously and intraperioneally at various periods after mixing. It was found that even after a few minutes the infectivity of the tumour cells was entirely destroyed, but although the injections were repeated no adequate degree of immunity was evoked. In spite of these adverse observations, it was (on the analogy of the results obtained with antiserum) considered worth trying whether by inoculating formalin into growing tumours *an effective vaccine could be produced in the living animal.*

(*b*) *Study of the effects of injecting formalin into growing rat sarcomata.*—Approximately 0·1 c.cm. (a large dose) of minced, actively growing J.R.S. (from 10 to 14 day old tumours) was inoculated into the flank of young adult black and white rats—i.e., the site at which it grows most vigorously. In a week's time tumours of about 1 inch in length and weighing roughly 1/150 to 1/100 of the animal's body-weight resulted. The material used in all these experiments was so virulent that natural regression very rarely occurred, and in 95 per cent. of cases the control animals died in three to four weeks. It will be appreciated that using a tumour of such virulence entails heroic dosage of formalin and a rapidity of judgment which would be unnecessary in the slower-growing tumours of man. Untreated controls were kept in each experiment.

Into six to eight day old tumours, formalin* diluted with distilled water, and in some cases with saline, was injected slowly and with as little pressure as possible. After many experiments 1 per cent. of formalin was found to be the most appropriate dilution. About 1 to 2 c.cm. of this solution was injected daily until the tumours ceased to grow and acquired a peculiar soft doughy consistency, which only experience can teach one to recognise. A considerable area of inflammatory thickening surrounded the tumours and no doubt this reaction aided in producing cure.

If the treatment is carried out skilfully and is stopped at the right time, regression takes place gradually (beginning after five or six days) and becomes complete without the occurrence of ulceration. If it is carried too far ulceration is apt to occur with the risk of prejudicing the subsequent immunity. Too prolonged treatment may also do harm by destroying many of the extravasated leucocytes which play an essential part in the process of cure. If, on the other hand, treatment is stopped too early the remnants of the very virulent tumour used may gain such an ascendancy that cure is unattainable even if the injections are resumed. The number of injections must be varied according to the progress of the case; in some instances only two or three doses of formalin are required, but generally five to eight injections and sometimes a dozen or more are necessary. The animals should never be injected when they are thirsty, since thirst increases the rapidity with which the formalin is absorbed into the blood. The first dose injected should be small, 0·5 to 1 c.cm., but a second injection may be given six to eight hours later when local œdema has appeared. The injections should not be given too near the skin in order to lessen the risk of ulceration.

In tumours treated by formalin in this way every grade of dilution of formalin must be present at some area or another. In some parts the concentration will be too weak to kill the cells, at other places so strong as to destroy the antigenic factor. In yet other areas the appropriate dilution will occur—i.e., a concentration of formalin just adequate to kill the cells, without destroying their antigenic constituent.

It is possible that a yet more effective reagent than formalin may be found, but where full-grown rats are selected and the tumour is not over 1/100 of the body-weight of the animal—i.e., 2 cubic centimetres or so in bulk—it is possible, after some months of experience, to obtain even with formalin well over 90 per cent. of cures. The subsequent immunity is of a very high order, for out of 43 animals cured and subsequently inoculated 40 were found to be immune—i.e., 93 per cent.

[1] Lumsden, T.: THE LANCET, 1926, ii., 112; Ibid., 1927, i., 116.

* Everywhere in this article the word "formalin" refers to the commercial product containing roughly 40 per cent. of formic aldehyde. The 1 per cent. formalin used for treatment contains, therefore, about 0·4 per cent. of formic aldehyde.

The details of all the completed experiments are as follows:—

Date of exp. in 1927.	Rats treated.	Rats cured.	Date of exp. in 1927.	Rats treated.	Rats cured.
21/3	13	8	17/10	7	7
19/5	8	5	24/10	5	4
26/9	24	17	31/10	3	3
4/10	10	10			

In all 70 animals were treated, of these 54 were cured—i.e., 77 per cent. It will be noticed that as the result of increased experience the percentage of cures rose in the last four experiments to 96—viz., 24 out of 25 tumours disappeared.

Subsequent Immunity.

Forty-three cured rats were inoculated on the same day—i.e., at varying periods after cure—with 0·1 c.cm. of J.R.S. fragments. Twelve normal and eight uncured treated rats were given a like dose of the same material as controls. The rapid growth in all the normal control animals showed how virulent the test J.R.S. fragments were. In every instance the inoculations into the cured rats grew much less rapidly than in the controls, but probably in most cases proliferation occurred for a day or two. The test tumours in cured rats could be divided into three more or less overlapping groups: (1) Those in which no increase in size was seen, the graft being imperceptible after a week or 10 days—(12 rats). (2) Those in which well-marked proliferation with increase in size of the graft took place for seven to ten days, but which thereafter regressed and had disappeared in from 14 to 21 days—(28 rats). (3) Those in which growth though slow was progressive (3 rats)—i.e., in 7 per cent. All the test tumours were measured every two to three days, and portions of the growth from typical examples of each of the three groups were removed for histological examination.

Histological Examination of Treated Tumours and of Test Implants.

(*a*) *Treated tumours.*—Twenty-four hours after 1 per cent. formalin has been injected a certain amount of hæmorrhage has taken place into the growth and in some areas many cells have pyknotic nuclei. Already round the outer edges of the tumour a dense concentration of leucocytes of all kinds has taken place. Over the greater part of the tumour, however, the sarcoma cells are still healthy and are actively dividing.

Later on, when regression is well marked, in progressively increasing areas death of the tumour cells has occurred, some have pyknotic nuclei, in many others the nuclei have entirely disappeared. A large army of leucocytes invades the tumour, and at length little but stroma and blood-vessels remain, these ultimately disappear, the whole growth becoming replaced by scar tissue.

These appearances resemble more or less those observed during the regression of a test inoculation in an immune animal, but the proof that immunity plays a large part in the process of cure does not rest on this similarity alone; it is demonstrable also in other ways. Thus if the serum of a rat whose tumour is disappearing as the result of treatment is applied to a culture of mouse cancer cells it damages them seriously. A normal rat's serum never does so. A further proof is that the formalin injections may be discontinued before the tumour has completely disappeared, and while many sarcoma cells are still alive. Once the formalin has definitely turned the scale of the battle between the tumour cells and the rat's defensive forces (antibodies and leucocytes) treatment should be stopped. The remaining portion of the tumour will regress without further outside assistance.

(*b*) *Test implants.*—Sections of many tumours at various stages of growth and of regression have been examined and the detailed observations will be the subject of a future communication. It may, however, be of interest to give here some of the facts, and the interpretations placed upon them.

1. Where a very high degree of immunity is present, as in the case of a rat cured of a large tumour by two injections of concentrated antiserum, the test graft disappears as rapidly as in a hyperimmunised animal. In such instances the inoculum regresses without any appreciable period of proliferation. The cells at the periphery of the graft, which attempt to invade the resistant tissues, are killed, and the whole inoculum is rapidly destroyed, death proceeding from the circumference towards the centre.

2. In animals less highly immunised—e.g., in cured but not hyperimmunised rats—the graft generally wins a local victory at first. Invasion of the normal tissues by the sarcoma cells succeeds, and a stroma is commandeered almost as effectively as in the normal unprotected animal. Within a few days however, reserves of trained leucocytes are mobilised round the tumour and sooner or later (7 to 21 days) in 90 per cent. of cases, the battle ends in victory for the animal and the test implant disappears.

Such regression is clearly not caused by the animal refusing in some mysterious way to furnish a stroma. Death is not due to simple inanition, for in that case the cells at the centre of the inoculum being least nourished would die earlier than those which obtain a subsistence by soakage of lymph at the circumference. The reverse is what actually happens. It is clear, therefore, that the peripheral cells which die first must be actively destroyed by forces other than starvation. The effective factor in rapid destruction of a graft is that the sarcoma cells are in a highly immune animal, unable to invade the body tissues successfully. Conversely in the unprotected animal, when successful invasion is achieved there follows an inflammatory reaction with formation of new blood-vessels and connective tissue and progressive growth ensues.

"*Metastatic*" *tumours.*—In some experiments just before, in others a few days after beginning treatment of a sarcoma of the right flank, a graft was implanted also in the left flank in order to simulate a metastasis. The study of this "metastasis" gave a very useful guide as to the rise and progress of immunity. In all cases the second implant grew for several days. Then if the right flank tumour was responding satisfactorily to treatment, the resulting immunity was evidenced by the cessation of growth and later regression of the "metastasis." If, however, the cure of the treated tumour was delayed the "metastasis" continued to grow and in some cases attained so large a size as to impede or prevent cure, presumably by absorbing the antibodies which were being produced in the animal. Since this experiment entails a struggle between opposing variable factors it is difficult to predict the results when using a tumour of great virulence. If, however, the appropriate conditions are attained, the results are interesting and convincing. In several cases the fact that the "metastasis" was seen to be regressing made it possible to stop the formalin injections into treated tumours earlier than one would have dared to do but for this indication of the onset of immunity.

Remarks.

When tested upon tissue cultures of normal and malignant cells it is found that formalin has little if any specificity in its action on cancer cells. It appears, however, to have the power so to kill these tumour cells in the body that they become antigenic. Absorption of the vaccine thus produced evokes a general active immunity of the most exquisite specificity. Reagents are produced which attack and destroy not only the remaining portion of the original tumour, but also any small coexisting untreated tumour which is present, without damaging any normal organ or tissue. The following points must be kept in mind: The younger the rat the more difficult it is to evoke immunity, and to effect cure. The smaller the tumour the easier it is to cause regression, but the less powerful is the subsequent immunity. There is, therefore, a time of election which is the most favourable for beginning treat

ent. In a rat this is when the tumour has attained, y, 1/150 of the animal's body-weight; in a human ing it would probably be earlier. The sooner eatment is stopped after cure is assured the more ective is the resulting immunity. Severe ulcera- n lessens the degree of immunity attained.

It has been impossible to try the curative effect of is treatment upon spontaneous growths on account the lack of material. A single observation is of erest in this connexion. In a rat which was ffering from a spontaneous adenocarcinoma of the east, the cure of an implanted J.R.S. by means of malin injections was followed by marked regression the spontaneous mammary tumour which is now ly about one-fourth of its original size and is inishing steadily though slowly. Since this is an lated instance, and may be an example of spon- eous regression, too much reliance must not be ced in its significance.

Vaccine treatment has not yet been fully investi- ed in carcinomata, and may conceivably be less plicable to these than to sarcomata, but judging m the analogy of antiserum treatment this is likely, for with the latter reagent cure was even re sure and easy in the case of the rat carcinoma 9) than when J.R.S. was the tumour treated. me cases of mammary cancer (M.63) in mice were ated with formalin, but the mouse is a very unsatis- tory animal for such experiments, its soft tissues d to ulcerate and do not retain injections well; o cancer of the breast is in mice very apt to invade peritoneum, a complication which makes treat- nt by formalin difficult and ineffective. More erse still is the fact that, like very young rats, e have rather feeble powers of producing active munity to tumours. In the last batch of mice ated, out of seven mice five appear to be cured, since some ulceration occurred in all of them, it ncertain whether these five will be immune when ed later.

Vaccine treatment of the kind referred to above t present only applicable to comparatively early small tumours, and such as could be easily oved surgically, but the fact that it is followed general immunity renders it when effective nitely superior to excision, since it precludes the sibility of recurrence. When a large tumour is ated in this way the treatment is unavailing. struggle for existence is taking place between tumour and the animal it infests. There is a it to the amount of protective material which animal can produce, and if the tumour is ond a certain size it appears to absorb the ensive reagents more quickly than the animal manufacture them. Progressive growth of the our and death of the animal ensues. To give the tment a fair trial it is therefore essential that it uld be applied in comparatively early stages of disease.

t has already been shown [1] that local inoculations specific antisera bring about the same train of nts as the injections of formalin referred to above. the two reagents formalin more readily destroys local growth but the subsequent immunity is re certain after cure by antiserum. A few recent ervations suggest that by concentrating antiserum say, one-fifth of its bulk, by evaporation at 37° C. vacuo, its local destructive power may be made to al that of formalin, in which case the specificity ts action on tumour cells would make it preferable reto.

Conclusions.

. By means of appropriately managed local ections of formalin into a tumour while it is still wing in the body of a rat, it is possible to damage e of the tumour cells in such a way that their ility is destroyed without annihilating the anti- ic constituent they have been shown to contain. sorption into the general circulation of the vaccine oduced gives rise to an active immunity which pletes the cure of the treated tumour and vents recurrence.

2. By vaccine treatment of this sort very virulent tumours (J.R.S.), weighing as much as 1/100 of the body-weight, were made to disappear. Of 70 tumour-bearing rats so treated, 54 were cured—i.e., 77 per cent. In the four latest experiments the percentage of cures rose to 96—i.e., 24 animals cured out of 25 treated.

3. Forty-three animals so cured were subsequently inoculated with grafts of the tumour concerned. In only 3 of these did the implant grow progressively—i.e., 40 (93 per cent.) of the rats proved to be immune.

4. It is possible that by pursuing the above line of inquiry a particular reagent yet more effective than either formalin or antiserum may be found. The general principle rather than the individual method is insisted on—namely, that by local treatment of a tumour *in corpore* a vaccine capable of evoking active tumour-immunity can be produced.

It is a pleasure to express my gratitude to Sir Charles Martin, F.R.S., director of the Lister Institute, for valuable advice and criticism. I thank my assistant, Miss A. C. Kohn-Speyer, B.A., for much skilled help, and especially for keeping careful records of all the experiments. By means of their grant to me the British Empire Cancer Campaign have made it possible for me to devote the whole of my time and energy to this research.

THE ZÜND-BURGUET METHOD IN CHILDREN.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,
CONSULTING AURAL SURGEON TO THE LONDON COUNTY COUNCIL.

THE following five cases demonstrate the value of the electrophonoïde treatment of Zünd-Burguet in cases of deafness in children, which have hitherto been considered as hopeless. The results encourage one to hope that a considerable percentage of the deaf children who, from the failure of all other treatments, have been compelled to receive their education by the usual methods employed for the deaf, may in future be so far restored to hearing as to be fit for education in normal schools for the hearing.

Five Cases Related.

CASE 1.—A. B., aged 16 (born 1910), was "perfectly normal" until five years old, when deafness began after whooping-cough and slowly increased. She was seen by four otologists (all on the staffs of large general hospitals), one of whom removed adenoids, and a second gave as his opinion that the deafness was due to "meningeal trouble." I saw her first in June, 1922, when inquiry into four generations of family history failed to discover any trace of deafness. The family doctor was of opinion that hearing was not entirely lost. Both drums were normal, and there was nothing noteworthy in the upper air passages. On testing, she could hear open vowels with the right and partly with the left ear. She was said to have heard sentences in the loud voice very close to, but I failed to confirm this. Bone conduction for the 35 seconds fork was R. = 12 in., L. = 22 in. By air conduction she heard, R. and L., from I C 64 to C 512—i.e., all in the area of human speech. Galton whistle was not perceived in any part of the scale. I gave it as my opinion that she would have to be educated upon deaf methods, and that an attempt should be made to develop the residual hearing by exercises combined with lip-reading. I saw her again in March, 1926, and found her reactions to tests much the same as four years previously. The Zünd-Burguet treatment was then suggested as—to me at that time—a rather unknown quantity that might be successful in developing her residual hearing, and which could, at any rate, do no harm. The suggestion was accepted by her parents and put in practice on March 8th, sittings being given five days weekly. On March 31st she could hear knocks on the door and the click of the electric light switch. During the whole period of the treatment, save when she returned home for the holidays, she was living with a trained teacher of the deaf. Mrs. Haine and her husband undertook to exercise her hearing, first by vowels, later by sentences. She was tested on April 2nd, two days after the completion of the first 15 sittings. It was then found that she could hear such sentences, spoken in a clear ordinary voice, close to either ear, as "How are you?" "When

do you go home?" "That was a spider." "It is a fine day," &c. Mrs. Haine reported that she could repeat sentences after her husband easily, and less easily after her, and she evidently heard men's voices better than women's. Her voice already showed less of the "dead" quality associated with serious loss of hearing. The treatment was continued until April 23rd, when the first course of 30 sittings was completed. She could then repeat any sentence, however nonsensical, given her at about 6 inches. Her voice was greatly improved. She went home for the Easter holidays, and not only heard her father's voice for the first time for some years, but could hear all he said to her. She resumed treatment on May 11th, and on July 23rd was hearing all sentences regularly at 6 inches as a minimum. On her return from the summer holidays on Sept. 23rd, the report was that she could hear her father at about 50 inches and, for the first time, she repeated my sentences, in ordinary low tones, at 12 inches. Treatment was regularly continued to Dec. 11th. On Oct. 11th she could repeat all that was said to her always at 12 inches with the right, and 8 inches with the left ear, and on one occasion remarked to me: "I hear differently now in the right ear. I really *do* hear." On Nov. 30th she heard a *whisper* close to the right ear. On Dec. 15th my ordinary voice was heard by either ear at a distance of 18 inches. The improvement appeared to be continuous, and she could hear a book read to her at from 8 to 12 inches. She resumed treatment after the Christmas holidays on Jan. 4th, 1927, when it was found that she could hear the slightly raised voice at 6 feet. After an operation on March 26th for appendicitis, her hearing diminished during convalescence, but completely recovered later. Altogether she had 182 treatments. She occasionally, during the treatment, complained of slight aching in the ears, and it was often noted that this occurred before a further improvement. This phenomenon is attributed by Zünd-Burguet to the stretching of adhesions in the tympanic cavity. In a case like this, in which the deafness had existed from early childhood, the daily exercises in speech, already alluded to, formed a valuable adjunct, since she knew words by *sight* only, either as spoken—i.e., lip-read—or written words, and it was necessary, therefore, to educate her in the knowledge of their *sound*. It may be added that Miss A. B. is an exceptionally intelligent girl, and had learned Latin and French by the oral method before she underwent the electrophonoïde treatment. At the time of writing (October, 1927) she has retained her improvement, and will later resume treatment with a view of a further increase of her hearing. Sincere thanks are due to the teacher and her husband.

CASE 2.—C. D., aged 6½ years. Bilateral deafness for some two and three-quarter years arising in the following manner. At 4 years and 3 months tonsils and adenoids were removed, and as he lay in bed recovering from the anæsthetic his thigh was severely burned by a hot-water bottle left in contact with it by a careless nurse. The burn was extensive, and became septic. He slowly became deaf from this time, and three otologists independently diagnosed the deafness as of auditory nerve origin, and agreed that there was nothing to be done. I first saw him two years and a half later. Both drums were normal in colour, lustre, inclination, and mobility, and nothing noteworthy could be found in the nose or throat. Bone conduction to the 35 seconds fork was R. = 14 seconds, L. = 21 seconds. No loss for low tones. Galton whistle R. = 1·7, L. = 1·5. The whisper was not heard by either ear. Ordinary conversational voice R. = 15 in., L. = 8 ft. Electrophonoïde treatment was commenced Oct. 13th, 1926, and on Nov. 3rd, two days after completion of the first 15 sittings, voice was R. = 3 ft., L. = 8 ft. On Nov. 20th he surprised his mother by hearing her whisper, his face being turned away. On the completion of 30 sittings, voice was R. = 8 ft., L. = 12 ft. Whisper R. = 1 ft., L. = 14 in. Bone conduction R. = 25 seconds, L. = 30 seconds. On Jan. 4th, 1927, he returned for a further 20 sittings, and it was found that he had gone back slightly, voice being R. = 3 ft., L. = 11 ft. Whisper R. = 9 in., L. = 1 ft. This second course was unfortunately interrupted by a severe attack of influenza. On his return on April 26th the hearing was R. and L. = 12 ft. Whisper R. = 10 in., L. = 17 in. A further course of 20 sittings resulted in voice R. = 12½ ft., L. = 15 ft. Whisper R. = 10 in., L. = 16 in. Bone conduction R. = 27 seconds, L. = 31 seconds. I did not see him again until Sept. 19th. His hearing had again retrogressed, and a thorough overhauling by Mr. J. E. R. McDonagh revealed the fact that he is suffering from a definite colitis with resulting chronic intestinal intoxication. He has been placed under treatment, and further electrophonoïde sittings have been postponed for three months.

CASE 3.—E. F., aged 8 years. Deafness after measles in 1925, was very ill for four or five days. Tonsils and adenoids removed three years earlier, and the evidence showed that he had been slightly deaf prior to the operation and had become worse after the measles. Could not hear low tones, such as the buzz of insects, had never hea the cuckoo, but could hear the lark and women's voic Of general conversation he heard nothing, and had lost t power of listening attentively. Late in speaking and ve indistinct up to three years, speech was still slightly defecti Drums showed good lustre and very slight indrawi Nothing noteworthy in throat and nose. Bone conducti to 35 seconds fork R. = 25, L. = 20. Lowest tone hir R. = 1 C 64, L. = 2 C 32. Galton whistle normal R. and Whisper R. = 45 in., L. = 5 ft. On August 24th, 19 the Zünd-Burguet treatment was commenced. After 6 sittings, whisper R. = 15 ft., L. = 8 ft. After 30 sittings was R. = 15 ft., L. = 9 ft. This was highly satisfacto considering that two otologists had pronounced the opini that treatment was useless, and that he would have to educated upon deaf principles. On Nov. 9th he return for a further 20 sittings, when it was found that not o was the hearing maintained, but that in the left ear it h increased another foot. At the end of this course t whisper was over 17 ft. in the right and over 10 ft. in t left ear. Seen on Feb. 28th, 1927, this improvement w maintained, he was reported as doing well at school, t that his hearing varied a little for different voices and could not always locate sounds. On May 30th I fou that the hearing was maintained, and he volunteered that had heard the cuckoo for the first time. He was n however, in good general health, and examination Mr. McDonagh revealed chronic colitis, for which he w placed upon treatment. He is now in sound health, has h no recurrence of the deafness, and is attending an ordina school.

The results obtained in these three cases impell me to consider the wisdom of testing the treatme in pupils who, after long trials of the methods esta lished by otological tradition, had been relegated failures to schools for the partially deaf. After co sultation with the deputy inspector of L.C.C. de schools, two boys were selected for experiment courses. Both were cases of so-called middle-e deafness, and the details of their treatment are brie as follows:—

CASE 4.—G. H., aged 11 years, was first seen Feb. 12 1924. He was stated to be deaf, which his mother deni Mouth-breather, with marked tonsils and adenoids. Ve difficult to test, but obviously very deaf. Certified as "ha of hearing," after removal of tonsils and adenoids and otl treatment had shown no result. On Nov. 17th hearing voice was R. = 4 ft., L. = 0. He gradually became wor and on Feb. 28th, 1927, hearing for the voice was o R. = 2 ft., L. = 0. After 15 sittings of the electrophono treatment it was R. = 3 ft., L. = 0. On the completion 30 sittings it was R. = 12 ft., L. = 0.

CASE 5.—K. L., aged 12 years. First seen Dec. 4th, 19 Then had a good voice, and had done fairly well in t infants' school. Drums markedly indrawn, throat a nose clear. His deafness varied. Raised voice was R. = 4 L. = 3 ft. He was certified for the front row of an ordina class, for revision after six months. This was done wi the object of treatment in the interval. On July 1st, 19 he was obviously more deaf, hearing the loud voice only 4 ft. Speech was now defective, and he did not appe to have received adequate treatment. Certified for "hard hearing class." On Feb. 21st, 1927, hearing for the ordina voice was R. = 2 ft., L. = 9 in., and the electrophono treatment was commenced. After 15 sittings hearing w R. = 2 ft., L. = 1 ft. 10 in. At the completion of 30 sittin it was R. = 2 ft., L. = 2 ft. The improvement in the l ear, although the hearing was more than doubled, w disappointing, but perseverance would probably be attend with more success. I am of opinion that this boy was example of chronic intestinal intoxication, a condition whi has, I believe, a very intimate relation with intractal chronic deafness.

Deductions.

The lesson to be learned from the five cases ju described is a very valuable one. They sugge that a considerable percentage of children sufferi with progressive deafness are given up as hopeles once the traditional methods of removal of tons and adenoids, with more or less regular inflatio have proved useless, when the Zünd-Burguet trea ment might give highly satisfactory results. It not unreasonable to suppose that the first, fourt and fifth cases of this series—a small series, I admi but one capable of great extension—could have be saved from the necessity of education on deaf lin by a timely application of the electrophonoïde. Sin the net cost of education of deaf children, as compar

with hearing children, according to the London County Council estimates for 1926–27 is, per capitam, as follows :—

	£	s.	d.
Elementary schools	15	7	4
Deaf schools	67	6	2
Partially deaf schools	49	13	1

It is obvious that the introduction of the electrophonoïde treatment into our treatment centres throughout the country would be attended by a considerable saving in the annual public expenditure, once the initial cost of apparatus and the training of operators had been defrayed. It would mean, in addition, a rise in the social happiness and potential civic efficiency of many more of our children. Cases 2 and 3 specially illustrate this latter point. Cases 4 and were experimental, and a continuance of their treatment by this method will probably bring further improvement.

An experience of 20 years' work among deaf children certifiable as deaf, within the meaning of the Act of 1893, has convinced me of the helplessness of otology before a considerable percentage of cases of non-suppurative deafness. I am certain that in many of these cases the electrophonoïde method would give excellent results; an opinion based upon two years' work with the apparatus, and the published papers of Raoult of Nancy, Helsmoortel of Antwerp, Lathcart of London, Ferguson of Jersey, and others.

In cases of chronic non-suppurative deafness, both in children and adults, there are other and more general causes at work than those usually described in text-books of otology, and I would draw attention to the widely different behaviour to local treatment of cases of catarrh of the upper air passages, the effects of which catarrh upon the ears is well known and accepted. There are plenty of cases in which the removal of adenoids and septic tonsils, the correction of nasal abnormalities (as deflected septum), and other conditions in the nose and throat (as chronic sinusites) are attended with excellent results, ranging from fair improvement to complete relief of the aural disability. But there remains a large —I am tempted to say a very large—residue of cases in which, in spite of all traditional treatments, there is progress from bad to worse to final severe chronic deafness. The otologist is often too prone to confine himself in his search for causes to the immediate neighbourhood only of the organ in which he specialises, and therefore fails to detect an underlying general cause. I am only too conscious of the fact that I have myself sinned in this way in the past. What is usually termed "constitutional treatment" is a vague shibboleth of the text-books which, when undertaken, is often merely perfunctory. Recent experience, of which Cases 2 and 3 are illuminating examples, has led me to the opinion that in those instances in which chronic catarrh persists after every treatment, operative, local, and so-called "constitutional," has been tried, the real cause may be, not in the upper air passages, or the middle and external ears, but in the intestinal tract.

LEEDS MATERNITY HOSPITAL.—With a bed capacity of 50, this hospital has 75 actually in use, and sometimes further accommodation to the extent of 10 per cent. is to be improvised. A quarter of the births in Leeds occur within its walls. It is now proposed to increase the accommodation to 103 beds, with an isolation block, a new operating theatre, and further room for the nurses and domestic staff.

WALTHAMSTOW, WANSTEAD, AND LEYTON CHILDREN'S AND GENERAL HOSPITAL.—The Duke of York, who was accompanied by the Duchess, recently opened the extension of this institution, which serves a population of over 300,000. The extension increases the accommodation from 50 to 98 beds, including ten private wards for paying patients. The addition also provides a new nurses' home, residential quarters for two house surgeons, a new casualty department, increased accommodation for out-patients, and a new X ray and radiological department. The works have cost £45,000.

NICOLL'S OPERATION FOR FEMORAL HERNIA.

SOME SUGGESTED MODIFICATIONS.

BY ARTHUR EDMUNDS, C.B., M.S. LOND., F.R.C.S. ENG.,
SURGEON TO KING'S COLLEGE HOSPITAL.

MUCH has been written in recent years about the operative treatment of femoral hernia, but most authors treat operations from below with scant consideration, as if they were quite archaic and of no practical value.

The Original Operation.

In 1906 Nicoll, of Glasgow,[1] published details of an operation which, in my opinion, was based upon sound principles in that, after dealing with the sac, he closed the femoral canal by suturing Poupart's ligament to the back of the pubic bone. He also suggested a method of dealing with the sac on the lines suggested by MacEwen for inguinal hernia, but I have not adopted this part of his technique, as it did not seem to offer any marked improvement on the old method of transfixion and ligature. I have, however, performed his osteofascial suture for over 20 years and have, I venture to think, found out for myself a few points in which his original methods may be improved.

My habitual procedure is as follows. A curved incision is made, as recommended by Sir Watson Cheyne, and a flap turned inwards, exposing the sac and the lower part of the external oblique. The sac is dealt with in the usual manner; it is allowed to slip back, and any tags of retroperitoneal tissue which are present are pushed back through the femoral canal. The anterior surface of the pectineus can now be quite easily exposed by stripping a little loose areolar tissue from its surface. The vein is held out of danger to the outer side, and the point of the knife is passed through the fibres of the muscle down to the bone; by cutting the muscle from without inwards the horizontal ramus of the pubis is exposed for about an inch. The problem which now presents itself is that of drilling two holes through this bone.

Drilling the Bone.

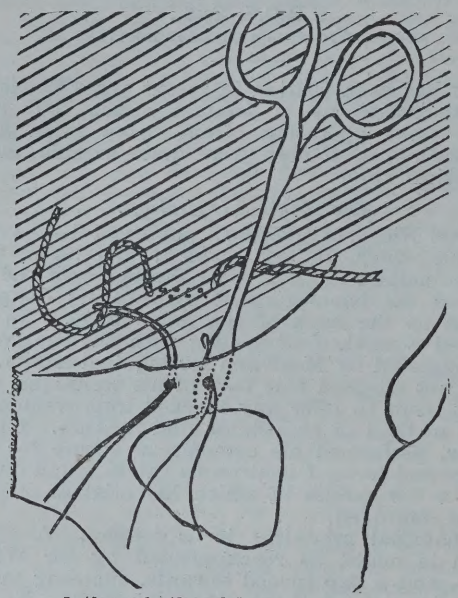
I have used many types of drill, but all had the disadvantage of penetrating the compact bone on the deep aspect of the pubis with a disconcerting jerk. I have never wounded anything, but I have had some anxious moments. Nicoll used a tongue depressor to protect the deep structures, passing it through the femoral canal to the deep side of the bone. This is, however, rather large for many cases, and I have generally used my finger. It is usually easy to feel when the drill is coming through, but at times the finger is in danger. Recently I have overcome this difficulty by using an ordinary carpenter's gimlet, which is passed through the bone without any appreciable pressure by simply turning it round and round. This tool as sold consists of a metal part riveted into a hard wood handle. These are fastened together by expanding the metal portion over a washer, after it has been passed through the wooden handle. A few touches with a file will remove this expanded portion, and the metal part will come away with a nicely squared shank, which fits into the ordinary chuck drill-holder that every instrument-maker sells. In addition to the gimlet, two pieces of annealed iron wire are required. These should be about 18 inches long and about as thick as the wire used to tie down champagne corks. They must be doubled in half and the loop thus formed crushed almost flat between the blades of a pair of artery forceps.

Having exposed the bone, the surgeon passes his forefinger to the back of the pubis, into the loose areolar tissue above the attachment of the pelvic fascia, which is not here attached to the margin of

[1] Ann. Surg., 1906, xliii., 114.

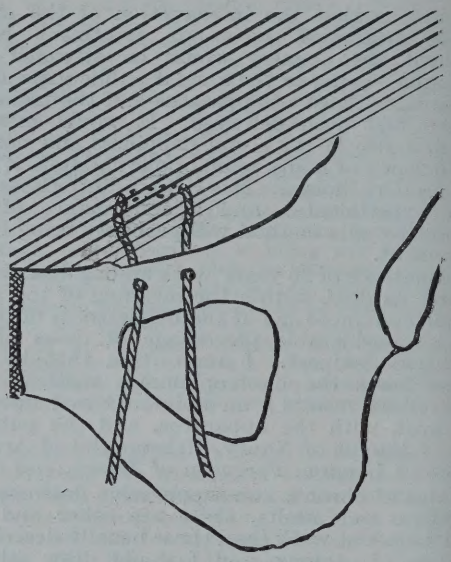
the pelvis, an anatomical condition which greatly facilitates this operation. If the femoral canal is too small to admit the finger readily there need be no hesitation in dilating it, as the subsequent stages of the operation will close it quite efficiently. The bone is now bored through in an upward direction with the gimlet, the point of which can be easily felt as it comes through the bone. When the gimlet projects well through all the blood is carefully mopped from the depth of the wound and the gimlet withdrawn. Before the field of operation has become obscured by fresh oozing, one of the loops of wire is passed through the hole in the bone and drawn up into the wound by means of a pair of artery forceps, introduced through the femoral canal. A few tags of retro-peritoneal tissue are often brought up also, but these are easily returned into their place. This procedure is repeated with the other loop of wire. A large needle threaded with very stout silk is now passed through the tissues above Poupart's ligament, picking up not only the external oblique but some of the fibres of the deeper muscles, and including in its grasp the upper and outer part of the internal pill of the external abdominal ring. The needle is no unthreaded and each end of the silk suture passe through the corresponding wire loop. By pulling o the loops the silk suture is drawn through the hol in the bone, so that there is now a strong mattres suture passed through bone and abdominal wal By pulling firmly on the two ends of this suture it possible to draw Poupart's ligament and the structur in immediate relationship with it to the back of th pubis. It is not enough to rely upon the parts bein brought into apposition by tying the silk suture there is so much friction over the rough surface the holes in the bone that unless the parts are brough into apposition by pulling on the suture, a gap wi be left which will not satisfactorily close the femor ring. It will be obvious, therefore, that strong sil must be used, and although I have always use very thick silk, I have never had to remov it subsequently. Indeed, one strangulated cas suppurated slightly without the stitch giving an trouble.

FIG. 1.



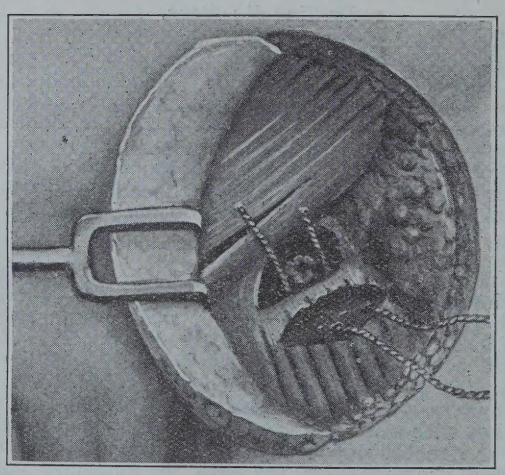
Suture passed through the abdominal wall and through the inner wire. The outer wire is shown grasped with the artery forceps by means of which it is to be drawn up.

FIG. 2.



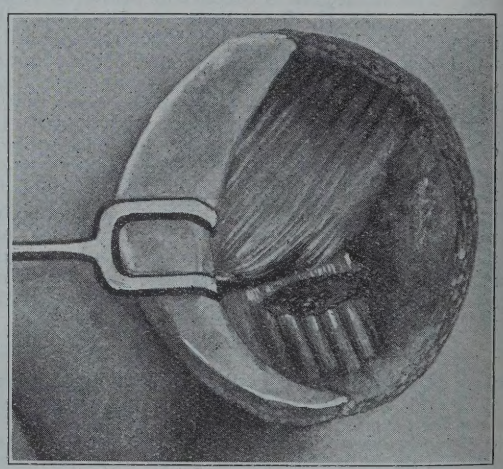
The suture passed.

FIG. 3.



The same stage as Fig. 2 shown in more detail. The ligatured sac is shown diagrammatically, but this should slip out of sight.

FIG. 4.



The operation completed.

Suturing.

I advise that the inner pillar of the external abdominal ring should be included in the stitch because I have seen an inguinal hernia follow this operation, and I believed that this was caused by the forcible dragging open of the inguinal canal. If it is not convenient to take in the inner pillar a few supporting sutures should be inserted uniting the pillars.

The points at which the bone is drilled must be selected carefully, so that when the operation is completed the femoral canal will be efficiently closed without any undue constriction of the vein. In very large rings I have put in two mattress sutures of this kind, or one mattress suture and a simple suture going once through the bone and picking up Poupart's ligament. When the suture is tied the wound can be closed as soon as any superficial bleeding has been dealt with. There is no need to suture the pectineus, as only its middle fibres have been divided. I am in the habit of incorporating a marine sponge in the dressing, an old-fashioned plan introduced, I believe, by Lister, which should be used more often than it is, for there is no difficulty in sterilising sponges, even though they cannot be boiled. In the bandage I like to incorporate one or more knotted turns, like the wool truss used by some people for babies.

Nicoll's method, in my opinion, deserves to be more widely used, and I hope that these modifications which facilitate the operation will make this most useful procedure more popular.

Clinical and Laboratory Notes.

A CASE OF PULMONARY INFARCTION COMPLICATING ENTERIC FEVER.

BY RICHARD MASSINGHAM, M.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, LONDON FEVER HOSPITAL.

THE following case has recently come under my observation:—

The patient, a man of 44, was admitted to the London Fever Hospital under Dr. C. R. Box on June 2nd, 1927. His illness had started, in the early part of May, near the Red Sea, with an ordinary febrile attack. He had returned to England on May 10th, and had remained more or less well ever since. Apart from general malaise, slight headache, and occasional diarrhœa, the most striking feature was a severe naso-pharyngeal catarrh; from this, however, he had suffered for some years. There had been some dirty muco-purulent sputum which was slightly streaked with blood. There were no definite physical signs in the lungs apart from a few crepitations at both bases. On May 30th the spleen became definitely palpable, and on the following day a rose-pink papular eruption was well marked. Although two blood examinations had proved negative, a diagnosis of enteric fever was made and the patient was transferred to hospital.

For this history I am indebted to Sir Charlton Briscoe and Dr. C. E. Lakin, under whose care he was before admission.

When first seen the patient looked very ill, with temperature 104·6° F., pulse 92, and respirations 20. The tongue was dry and coated, the abdomen moderately distended, and the spleen just palpable. Several rose-pink spots were present on the back and front of the chest and abdomen. Examination of the chest showed a few crepitations and scattered rhonchi over the lower half of the right chest and the base of the left lung. A Widal reaction now showed *B. typhosus* to be agglutinated in a dilution of 1 : 2000; the paratyphoid group negative. The patient, apart from a general feeling of malaise, complained chiefly of a troublesome cough and the expectoration of blood-stained muco-purulent sputum, examination of which showed the predominant organism to be a hæmolytic streptococcus with no typhoid or tubercle bacilli.

During the first three days in hospital the sputum became more heavily blood-stained, and the patient had two rigors, the temperature on one occasion falling to 96°. On June 6th he complained of pain in the right side of the chest. Examination showed imperfect movement on the right side, a dull percussion note over the lower lobes, a normal vocal resonance, and a friction rub, heard best just below the axilla. The patient was then expectorating almost pure blood, with temperature 102°, pulse 100, and respirations 30. On the physical signs and symptoms a diagnosis of pulmonary infarction was made. A careful examination of the body showed no evidence of arterial or venous thrombosis.

For the next three weeks, except for a slight but steady rise in the pulse-rate, the general condition and physical signs remained almost stationary. The temperature remained at the steady level of 102°–103° in the evening, with morning remissions of 2° or 3°, while the respirations remained about 30. By June 29th, however, the apex-beat had moved half an inch outside the nipple line, and the breath sounds had become fainter, although the vocal resonance and fremitus were still almost normal. Pus withdrawn by an exploratory puncture yielded typhoid bacilli.

On the following morning Mr. Maynard Smith resected a portion of the sixth rib, let out about three pints of pus, and inserted a large drainage-tube 5 in. long. For the next few days the pleural cavity was irrigated in the usual way with eusol until the washings were returned clear. About five pints were usually needed. During the wash-out on July 9th the patient suddenly became cyanosed and collapsed, and expectorated some sputum smelling heavily of chlorine. Apparently a communication between the lung and the pleura had been established. Eusol could, therefore, only be used in small quantities at a time. To keep the pleural cavity as clean as possible, a long small bored tube was stitched into the drainage-tube and then brought outside the dressing, so that, without disturbing the patient, small quantities of eusol could be injected day and night into the pleural cavity and allowed to drain into the dressing. Even then the patient sometimes complained of a taste of chlorine in his sputum.

During the next fortnight the general condition improved, the temperature started to fall, and the pulse-rate became slower. On July 21st, however, the patient during a fit of coughing expelled through the empyema opening a strip of lung 5 in. by 1 in. by 1 in. He said he felt "something give way," but beyond a little breathlessness his condition remained unaltered. Dr. J. Bamforth, who kindly sectioned a portion of the specimen for microscopical examination, reported that the blood-vessels were thrombosed, and the tissues had undergone coagulation necrosis. The temperature finally became normal on August 7th, and the tube was discontinued a week later. The patient was allowed up on August 23rd, and discharged from hospital on Sept. 27th.

During the last month in hospital the upper lobe of the right lung had expanded almost completely, and the air entry into the lower lobes had considerably increased. Diminished movement of the right half of the diaphragm was all that could be seen by a screen examination, while an X ray plate showed a small opaque mass in the lower lobe (apparently a scar) to which the diaphragm was attached.

So few are the recorded instances of pulmonary infarction in enteric fever that it must be considered rare. The references are confined to a few lines, with no mention of the time of onset, treatment, or prognosis, and appear to be the results of post-mortem examinations. Dr. Sidney Phillips recorded at the Clinical Society in 1905 a case of typho-pneumonia, where small hæmorrhagic infarctions were found microscopically scattered throughout the lungs.

H. Vincent and L. Muratet, in their book on typhoid and paratyphoid fevers, state that although the *Bacillus typhosus* may be present in the lungs, it is rare to find it in the sputum-cup; and it is of interest to note that in the case described above the bacillus was found in the pus from the chest but not in the sputum.

The complication of broncho-pleural fistula considerably increased the difficulty of washing out the pleural cavity, but the necessary alteration in treatment was one of degree and not of kind. The question of prognosis, however, presented great difficulty, since pulmonary infarction from any cause has a high mortality.

I am indebted to Dr. C. R. Box for permission to publish this case.

A NOTE ON
TWO UNUSUAL CASES OF FEVER.

BY E. WORDLEY, M.D. CAMB., M.R.C.P. LOND.,
PATHOLOGIST TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

WITHIN the past two years I have seen two cases of obscure fever which presented several points of interest. They had almost exactly similar symptoms, and the disease in each case ran a very similar course, so that a detailed description of only one will be given.

The patient was a man aged 36, who, except for a holiday in Norway and Switzerland for winter sports two years previously, had not since been abroad. He was taken ill with malaise, pain in the limbs, headache, and sweating. For the first week he thought he had an influenzal attack, and went about his business without consulting anyone. Soon he became so weak that he went to bed and sought medical advice. When first seen he had a coated tongue and it was noted that his temperature rose very regularly to about 101° F. at about 5 P.M., after which he sweated profusely. He was very thirsty and was constipated. The liver and spleen were not enlarged. Fifteen days from the initial symptoms the fever subsided and he made an apparent recovery, though he still complained of headache and considerable lassitude. He was then vaccinated against small-pox, as there had been a case locally. The vaccination took successfully, and he appeared to be recovering, when, eight days from the fall of temperature already noted, he had a return of the fever and sweating. Pains in the joints were especially marked, and there was swelling of several of the larger joints, which quickly subsided. At this point a tentative diagnosis of an enteric infection was made, and some blood sent to me for agglutination. It proved to be negative to the enteric group of organisms. About this time I saw the patient myself, and further investigations were made.

The blood picture was as follows: red cells, 5,100,000; hæmoglobin, 82 per cent.; leucocytes, 5200; polymorphs, 39 per cent.; lymphocytes, 52 per cent.; and hyalines, 9 per cent. The blood on culture proved to be sterile. Nothing abnormal was found in the fæces either microscopically or on culture. The urine contained one or two pus cells, but was sterile. A faint trace of protein was present. His serum agglutinated *Micrococcus melitensis* up to a dilution of 1/400, 1/800 being negative; the serum was put up both heated at 55° C. for half an hour, and unheated, and the same result was obtained in each case. On further inquiry no history of any abortion amongst cows was obtained either at the farm that supplied the patient with milk or at any other farms in the district. In the present case this negative evidence is reliable, since the patient lived in a small country town, and it was easy to trace all the milk supply. No goat's milk had been taken. Unfortunately no cultures of *Bacillus abortus* were available at this time, and by the time I had obtained these the patient refused to be bled again.

The fever continued altogether for about two months, slowly subsiding, but a considerable degree of weakness was left, and as the patient went on a long sea voyage it was impossible to get again in touch with him. He was treated with intramuscular injections of nuclein, though these appeared to make little difference to the course of the disease.

The second case, seen two years ago, in the middle of 1925, was almost exactly similar in every respect; the patient had never been abroad, the same end-point for agglutination against *M. melitensis* was obtained, and the other negative findings. This patient, however, made a more rapid recovery, and was well, except for very slight lassitude, in a month. At that time the prevalence of *B. abortus* in cow's milk had not been recognised, and no effort was made to test the serum for agglutinins to this organism.

In view of two very similar cases recently published by J. Bamforth,[1] one would suppose that in these two cases the fever was due to infection by *B. abortus*, and it is regretted that no more precise investigations could be made. Further, it seems probable that if a due consideration of the history and clinical condition could be always obtained by the clinical pathologis performing the laboratory investigations, more case of obscure fever might be found yielding indication of being undulant fever. There is no question bu that these two cases were clinically quite characteristi of this disease. The further point that arises, howeve is what importance is to be attached to a positiv agglutination against *M. melitensis* in a dilution c 1/400. Is this sufficient in cases of this type t justify a diagnosis of undulant fever?

[1] THE LANCET, 1927, i., 819.

A NEW SITE FOR ONCHOCERCA VOLVULUS

BY N. A. DYCE SHARP, M.R.C.S. ENG.,
MEDICAL OFFICER, WEST AFRICAN MEDICAL STAFF.

Onchocerca volvulus, both male and female, hav hitherto been found only in subcutaneous tumour and these tumours are still regarded as the sol characteristic of infection by this worm. Yet th tumour palpable beneath the skin has never bee found in more than 50 per cent. of those persons wh exhibit the larvæ in the skin. In actual practice i is found that of 100 persons who show a skin infectio with embryos of *O. volvulus*, only 30–40 will hav tumours which are palpable even after prolonge search. The commonest sites for these little tumou are over the ribs in the axillary line, over the anteric superior spine of the ilium, and over the great tro chanter of the femur. They may, however, be foun in any region rich in lymphatics, and the ankles elbows, knees, and even the scalp may at times b selected. It is clear, therefore, that the visible o palpable nodules under the skin are not the onl sites in which the parent worms can lodge, copulat and reproduce their young. For if only 40 per cen of persons exhibiting embryos in the skin hav subcutaneous nodules containing the parent worms in the remaining 60 per cent. the adults *mus* exist in the deeper tissues. But they have never bee found there.

In the case here recorded no nodules could b detected after prolonged and repeated examinatio but the volvulus embryos were present in a fragmen of skin removed from the back.

The patient was admitted to hospital with an ulcerate foot, resembling a Lisfranc amputation, which had sup purated for months. He was unable to describe how h came to lose the front half of his foot, and it can only b surmised that it was due to yaws, which is often fairly pain less in its mutilations. After a few days the ulcer becam cleaner and showed signs of healing with injections o novarsenobenzol. At this time the "amputation" stum was covered with granulation tissue, and none of the frag ments of the metatarsal bones were visible. Boric fomen tations were applied twice daily, and when removed wer usually dry. The dresser to the case noticed, howeve that there was always one spot which was wet. It was the observed that at this point, almost in the centre of th wound, there was a drop of milky fluid, and a slender thread half an inch long, was extruded. For several days th dresser had been dragging on this thread and removin as much as possible. It proved to be part of a femal *O. volvulus*, and from the portion removed numerou embryos made their escape into the saline in which i was placed. The worm could not be extracted whole, bu half to one inch continued to be extruded for several mor days. It was estimated that about eight inches of worm was removed piecemeal.

Owing to the condition of the parts it was impossible t identify the exact locality from which the worm emerged but in a normal foot it would have been below the secon and third metatarsal in the fibres of the flexor brevi digitorum.

This case is also interesting because the presenc of the worm in the centre of the wound, continuall ejecting larvæ, appeared to have no deleteriou effect on the general healing process, which proceede normally. It resembled, in fact, the behaviour o *Dracunculus medinensis* in everything but this, an it might well have been confused with this worm ha it not been for the microscopical findings.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF NEUROLOGY.

A MEETING of this Section (to which members of the Medico-Legal Society were specially invited) was held on Dec. 8th, under the chairmanship of Prof. EDWIN BRAMWELL, the President, and later of Dr. GORDON HOLMES. A discussion on

TRAUMATIC NEURASTHENIA AND THE LITIGATION NEUROSIS

was opened by Sir FARQUHAR BUZZARD, who said that the subject was one which had produced much confusion in the minds of doctors as well as lawyers. All knew, he said, the clinical picture of the worried patient, complaining of insomnia, dreams, pressure-headache, depression, giddiness, phobias, and loss of memory and concentration. He submitted that this condition was a mental disorder, an anxiety neurosis following an accident for which someone else was responsible. It was just as likely to appear in the absence of any physical lesion, and indeed rarely developed after serious physical injury. It did not follow hunting accidents, for which only the rider or his horse was responsible. It might be encountered after injuries to any part of the body, but was common after blows on the head or spine, because these were associated in the lay mind with terrible disablement. An important ætiological factor was the fright produced by the accident; this was unfortunately disguised under the term "shock." The neurasthenia of workmen's compensation cases was often the cumulative result of many small factors and of suggestions from friends, especially if the victim were past the age when his value in the labour market might soon decrease. To the lay mind trauma was still the most important universal ætiological factor in medicine, as it was in the medical text-books of 50 years ago. The psychopathological factors concerned in the production of traumatic neurasthenia were: fear at the time of the accident, anxiety as to possible consequences to health, the subconscious desire to safeguard the future, the sense of injury, the knowledge that the responsibility for the accident lay on some-body else's shoulders, the ignorant interpretation of symptoms, the injudicious remarks and advice of doctor and friends, and the worry of litigation. Whether or not this mental disability could be legally regarded as a result of the accident was a question that had aroused some doubt in judicial minds. A lawyer's letter had put it thus:—

"The employer's case is that the man's inability to work is caused by brooding over the effects of the accident, and that he is suffering from weakness of will and a fixed but erroneous idea that he is a chronic invalid. If they establish this proposition then the court would have power to refuse further compensation. If, on the other hand, this man is suffering from neurasthenia, as we are advised, he is then entitled to a continuance of the compensation."

To Sir Farquhar Buzzard's mind, however, the alternative diagnoses therein offered meant one and the same thing. The problem was important, both economically and ethically, and the solution did not lie entirely with the lawyers. If doctors took as much care to prevent infection of the patient's mind with fatuous and morbid ideas as they did to prevent infection of his physical wounds, the seeds of traumatic neurasthenia would rarely be sown. Doctors obscured the issue by talking about shock when they meant fright, and by treating established neurasthenia with a weekly bottle of medicine and the advice to take outdoor exercise. Were it practicable for the law to refuse to recognise mental disability traumatic neurasthenia would soon become very rare. The practical difficulty of diagnosis and the conflict of medical evidence would, however, remain. The difficulty would never be satisfactorily settled until diagnosis were submitted to medical instead of legal jurisdiction. If, on the other hand, the law regarded the accident as responsible for all subsequent disorders of the mind, the workman who brooded over his injury and harboured erroneous ideas of chronic invalidism would be as justly entitled to prolonged compensation as the sufferer from traumatic neurasthenia.

The Lawyer's Point of View.

The Right Hon. H. P. MACMILLAN said that the problem was on the borderline of law and medicine, and was of peculiar interest. It was part of the daily routine of a judge to determine what was and what was not the direct consequence of a wrong or tort or accident. The legal doctrine applied was the "doctrine of remoteness." That task of discrimination had constantly to be made in almost every department of commerce. In this instance the plaintiff would have suffered, possibly, no direct physical injury, but a pathological state of mind had supervened which would not have supervened but for the occurrence. It was a consequence of the occurrence because of the mental habit of the patient, who, through want of robustness or some other reason, had proceeded to brood over the occurrence and had created a "grievance complex." He had actually contributed through his own deficiencies to the creation of the state of mind that was pathological. Lawyers had to be rough and ready; the foot-rule of the law was not very delicately adjusted to measure electrons and ions. The law was not and never could be an exact science; it had to get on with its business. A very good criterion was ordinarily applied by the courts. Any person could recover damages in respect of a breach of contract or tort when the consequences were the "natural and probable consequences of the occurrence." This was easy to formulate, but in practice was often difficult to apply. The law said that, if a person chose to assault a fellow citizen, he must take his chance of that citizen's having a peculiarly thin skull, so that the consequences of the assault might be unexpectedly serious. That was very good common sense. In the same way railway companies must take their passengers as they found them, including their previous dispositions, peculiar characteristics, and mental outfit. The law said that a chain of consequences might be broken by the introduction of a new cause—"novus actus interveniens." If the patient's condition were due to the subsequent introduction of a new element the patient himself doing something, then the law would hold that the consequences were not directly and naturally attributable to what the railway company had done. The task was always, therefore, one of discrimination. The function of the doctor lay in assisting the court to determine whether or not in any given case the symptoms could or could not be described as "natural and probable consequences of the occurrence"; at that point medical men could make a great contribution to the course of justice. The honest expert witness was indispensable for the administration of justice. Evidence of opinion was absolutely unallowable in ordinary matters of daily life, but where judge or jury might not be presumed competent to draw inferences—e.g., in the realms of science, skill, or art—expert evidence of opinion was welcomed from assessors, referees, or the expert witness in the box. The real vice of the situation at present was the theory that had grown up that the expert witness was in any sense an advocate. He was nothing of the sort, and he ought to give his unbiased view honestly and sincerely, without fear or favour. The scandal—if scandal there were—of the conflict of medical evidence had largely arisen as the result of this misconception of the rôle of the expert witness. The court was entirely at the mercy of the medical evidence put at its disposal; it was a fundamental principle that the judge proceeded entirely on the evidence put before him, and not on his own opinion. A very high responsibility, therefore, rested on the medical expert. The original crude view of the law had been

that unless the victim could show a definite physical lesion he had no claim. The law had now advanced beyond that point, and was learning to note the finer shades of medical opinion, but it would never be possible entirely to reconcile the medical and legal points of view. The former was necessarily scientific and exact, the latter was neither. Mr. Macmillan was not sure that it would be right to delegate the question of consequence to a body of medical men not subject to cross-examination. It was better for cases to be decided by rough justice than to drag on interminably. The problem was one of cause and effect, and he would prefer that it should be settled by a court of law with the assistance of expert testimony.

Sir JAMES PURVES-STEWART distinguished between traumatic neurasthenia and litigation neurosis. The former was a bona fide medical illness, the latter was a legal complaint—in both senses of the word. In the courts they tended to overlap, but an effort should always be made to differentiate them. Many a straightforward medical affair became contaminated with the toxins and antitoxins of the law. Litigation neurosis might be compared with an innocuous drink to which various exciting ingredients were added at the Bar, so that the resulting cocktail was both interesting and expensive. When the Workmen's Compensation Act became law it soon became evident that the average duration of disability after simple injuries had risen considerably. Modern education had broadcast the glad news of "traumatic neurasthenia," and everybody had heard of the victim of a railway accident who, on being asked if he were hurt, replied: "I don't know until I have consulted my solicitor." Nervous symptoms after accidents were of two kinds: (1) actual physical injury, concussion, or commotion to the nervous system, clearing up under treatment in a few days or weeks, in the absence of an atmosphere of litigation; (2) nervous symptoms due to the expectation of financial solatium, real enough to the patient but produced by the novus actus interveniens—viz., suggestion. Commonly the production or persistence of symptoms was unconscious, and the patient gradually built up a compensation hysteria persisting so long as hope of pension or grant remained. This neurosis was not really the result either of trauma or of fright, but resulted entirely from the suggestions of outside people. Medical treatment was of no avail, but as soon as the case was settled it became unnecessary. Of 17 cases recently investigated 10 had disappeared from medical care immediately after the verdict and six had left definite records of prompt return to work. The remaining case had drawn disablement pay for five and a half years and then had lost his pension, whereupon he had calmly resumed work. A pension was a worse form of compensation than a lump sum, for the patient had to "earn his pension."

Dr. RISIEN RUSSELL said that there was no more difficult problem in medicine; he had always wished that there might be medical assessors rather than expert witnesses on opposite sides. The picture so typical of litigation neurosis was also encountered in private practice apart from compensation. The medical man representing the Company was sometimes to blame, as well as the solicitor and friends of the patient. Dr. Russell had seen incredulity, brusqueness, and once even brutality in the way in which this doctor approached claimants. Such behaviour aroused fear of being "done down" and exaggeration of symptoms, and also stimulated the protective instinct of the family doctor, so that the seed sown by the solicitor was nurtured. Physical signs associated with traumatic neurosis were tremor and exaggeration at first, and later marked diminution of the tendon-jerks. The consequences of shock were worse in old people, and arterio-sclerosis often came into the picture. Ultimate mental and physical deterioration might follow accidents where there was no question of litigation. The victim of a fall in the hunting-field, moreover, was free from the financial anxiety which played an important part in the production of traumatic neurasthenia. Dr. Russell pleaded for consultation between the medical officers of the two sides; this would save much litigation.

Dr. W. A. BREND said that the number of cases referred to him as referee under the Workmen's Compensation Act had shown an extraordinary decline in recent years. This indicated that compromise out of court was increasingly common, probably because both sides realised the potential pitfalls and the difficulties of representing a case adequately, and also because of the belief that prompt settlement would lead to rapid recovery.

He quoted the case of a workman who had fallen from a ladder and developed traumatic neurasthenia. His medical witness had given evidence badly, while the doctor appearing for the employers had carried all before him and roundly declared that the man had tabes, describing the absent reflexes, &c. So effective had he been that plaintiff's counsel had accepted the fact of tabes and based his case on the argument that the accident had accelerated or accentuated the disease. Dr. Brend had taken an opportunity to examine the man and had found his knee-jerks and pupil reflexes normally present. He communicated his finding to the judge, who was thus placed in a most difficult position, for no evidence had been brought against the existence of tabes. "From a legal point of view," said his lordship, "he has locomotor ataxia and he has got to have it." The learned judge had finally persuaded counsel to reach a settlement without calling on him for judgment.

The Ministry of Pensions had experimented carefully with the "lump sum" treatment of war neurasthenics, but so many of the men had returned in spite of receiving a final compensation, that the method had been discontinued as a failure. Removal of anxiety was not sufficient to clear up war cases, but they were men who had had a very bad time and there were not many of that type in civil life. It was doubtful if the term "traumatic neurasthenia" could rightly be applied to those cases whose symptoms disappeared on receipt of compensation.

Dr. W. SALISBURY SHARPE divided traumatic neuroses into: (1) functional paralyses; (2) functional or hysterical contractures affecting a limb to which there might only have been the slightest injury—the contracture might show a tendency to indefinite spread; (3) liability to true hysterical or hystero-epileptic seizures; (4) definite persistence of a symptom long after complete reparation had taken place; (5) alleged spread of symptoms, especially pains and paræsthesias, to the opposite side or to other regions beyond the injury; and (6) psychoses. Lawyers spoke of shock in a way that showed great lack of appreciation of its medical meaning. True surgical shock greatly diminished suffering, both mental and physical. Most of the neuroses after injury were the effects of fear. The worst case of shell-shock he had ever seen had been in a man who had never been nearer the war than Plymouth. An important sign, and sometimes perhaps a cause of traumatic neurosis, was sugar in the urine; a modified diabetic treatment sometimes benefited the nervous symptoms. Endocrine disturbance, usually hyper-thyroidism, might also be present. Fear was an ætiological factor both in diabetes and in Graves' disease. Litigation neurosis was occasionally fostered by doctors. He had rarely seen real "advocacy" in an expert witness; what was sometimes mistaken for it was the fact that medical men might honestly come to different opinions.

Sir WILLIAM WILLCOX spoke in favour of the final decision being left to judge and jury.

Sir FARQUHAR BUZZARD, in reply, again asked that the legal mind should decide where the responsibility for the whole train of effects lay. He did not think the Ministry of Pensions cases comparable with those he had described, as so many other factors came in.

Mr. MACMILLAN, in reply, said that all professions were apt to require from other professions a degree of exactitude of which they were not themselves capable. It was not possible for a lawyer to answer Sir Farquhar

Buzzard's question categorically, or to prescribe a formula for attributing responsibility. All the lawyer could do was to proceed on the evidence, and so hand the ball back to the doctor. He submitted that there was no true distinction between the physical and the psychological. The pathological psychological state, if all were known, would be found to be associated with some kind of undetected physical injury in the region of the brain. The discussion might aptly be concluded with the legal phrase: "Cur: adv: vult"—"The court will take time to consider judgment."

SECTION OF ORTHOPÆDICS.

AT a meeting of this Section held on Dec. 6th, Mr. W. ROWLEY BRISTOW, the President, being in the chair, a discussion on

FRACTURES OF THE SPINE.

was opened by Mr. GEOFFREY JEFFERSON (Manchester). Injury to the head was, he said, very important as a cause of cervical fracture or cervical dislocation. Direct violence to the spine was always an uncommon cause of vertebral disruption, and most spinal injuries were caused by force applied at a distance from the spine. If the injuring body was hard, and particularly if it struck at high velocity, a fracture of the skull would result and the full force of the injury would be absorbed by it. If, however, the wounding object was soft and very heavy, the spine—particularly its cervical portion—would be the part to sustain injury. In rare cases the head might be "mushroomed" down on to the spine, and then a ring of bone was driven around the foramen magnum up into the skull. Usually the bone in this area offered resistance, and if the skull failed to break elsewhere, the force acted on the spine. Perhaps in that case the atlas would be broken, or possibly some lower vertebra.

Mr. Jefferson explained that the vertebral column consisted of two parallel fused cylinders, of differing structure and purpose. The anterior consisted of the vertebral bodies and intervertebral discs, and its general purpose was to support weight. From the neural arches a number of transverse and spinous processes were thrown out, their chief purpose being to allow of muscular attachment. If the spine was violently compressed from above, the anterior pillar gave way more rapidly than the posterior, because of its spongy bone and the intervertebral fibrocartilages. For this reason flexion followed immediately on compression. The neural arch contained a considerable cancellous element. The tendency of the vertebral column to flex when compressed was aided by the protective reflex described by Magnus, by which any unexpected touch on the head caused the person to bend forward suddenly and involuntarily. Flexion of the neck alone by a strong driving force applied to the head would result in a dislocation, roughly at the junction of the middle and lower thirds. If the neck remained upright and the head itself was violently extended or flexed, a common result was a fracture of the odontoid process. Violent extension was a much more uncommon mechanism of spinal injury than flexion, and introduced the question of torque fractures of the pedicles. Sometimes severe injury followed slight movements, as in the case of a woman brushing her hair, or in diving. Kimmell's disease, which was described before the days of X rays, was a wedge compression fracture, a so-called spondylitis traumatica.

With regard to treatment, he said, the ideal always in the mind of the surgeon was reduction, but the cases one most wished to reduce were the hardest to deal with in that way. Most orthopædic surgeons seemed to have formed the opinion early in their career that they would have fractured spines with cord injury by operation, but the resultant mortality had cured their optimism. In a series of 85 patients, 16 died, 16 of them in the first week, and he was sure that none of those would have been saved by operation. Therefore operation should only rarely be undertaken, and only in cases in which pressure could be proved to exist. The general surgeon often erred because he was so apt to regard every case of fracture of the spine as a case of pressure. It was impossible to know from the skiagram what cases sustained damage to the cord.

The Neurological Standpoint.

Dr. GEORGE RIDDOCH said that all would agree that the more important consideration in these cases was as to whether or not the cord had been damaged. The crux of the matter, therefore, was, what to do if the cord was damaged, and he considered the subject largely from this attitude. The most common hæmorrhagic disturbance was the distribution of minute hæmorrhages in the cord in the region of the injury. Part of the disturbance of function in cases of spinal injury was transient and physiological, due to œdema, &c., and only part was the result of permanent structural defect. In the final stage of severe cases sepsis usually played a part, but even these patients might live a long time. Cadwallader had had a patient who lived 23 years after she broke her back. It was often a difficult problem to decide what was the exact level of the main spinal injury. Diagnosis of this depended on three groups of changes: sensory, motor, and reflex, the sensory being the most valuable. Hæmorrhage outside the cord did not cause spinal compression. Indriven fragments might look like a tumour in the skiagram, and if they caused pressure symptoms it was only in a passive way, and they did no more than cause fibrosis or a local encystment of spinal fluid. Under no circumstances should operation be done in these cases during the period of spinal shock—i.e., not within two to six weeks after the injury. After this period the indications for fairly early operation were: (1) the presence of gross bony deformity; (2) an arrest in the recovery process or an increase in the symptoms after a latent period; and (3) the presence of severe, persistent root pains. Operation should not be attempted if the cord was found to be completely divided by gross displacement of vertebræ and if there was failure of conductive power. There was more justification for operation when late paralytic troubles supervened, such as progressive meningitis circumscripta serosa, with increasing root pains spreading upwards and downwards.

Discussion.

Dr. BERTRAM SHIRES, speaking as a radiologist, urged the routine skiagraphy of all cases of injury, not only for ordinary diagnostic purposes, but from a medico-legal standpoint. So frequently when a case came to court no radiogram was available, when that would have been a vital factor in the decision.

Dr. GEORGE STEBBING gave an analysis of cases of spinal injury in the Lambeth Hospital, remarking that there had recently been a steady increase in this class of case, probably due to street accidents being more common. Of 32 cases admitted in the last three years, 14 had gross injury to the spinal cord. Five of them died in hospital, one 50 years after the injury, one 122 days after the injury, and others eight, two, and one day after being injured. Only a minority of spinal fracture cases were associated with gross nerve lesions. The decompression operation had not proved of value in the series he had come into relation with. He had never seen a case of this kind die of bedsores or pneumonia; the great factor in the final stage was pyelonephritis, which was very difficult to prevent.

Mr. THOMAS OPENSHAW agreed that in most cases of spinal injury the final factor was pyelonephritis. Prolonged immobilisation was essential for the recovery of many of these fracture cases. Stereoscopic skiagrams should always be taken. The orthopædic surgeon should especially be au fait with cases of injury of the spine in which there were no nervous symptoms. He related some interesting cases of his own.

Mr. ST. J. D. BUXTON showed skiagrams of a number of cases of his own which had presented problems in diagnosis and treatment. In regard to treatment, apart from reduction, he said, three things had impressed him: (1) the condition of the patient's respiratory system, (2) the abdominal condition, (3) the presence of sores. In cases which showed a prospect of recovery, the condition of the bladder should receive special care. He feared that was not always the case.

Dr. J. F. BRAILSFORD also showed a series of skiagrams of cases of spinal injury, deducing the lesions of each.

Mr. J. EVERIDGE concentrated on the seriousness of the urinary symptoms in spinal injury. Early catheterisation very often introduced sepsis. Sir J. Thomson-Walker had laid stress on the value of early suprapubic cystotomy, and the speaker thoroughly agreed with him.

Mr. BERNARD ROTH concluded the discussion by describing skiagrams of two cases in his own practice.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society held on Dec. 12th Mr. HERBERT W. CARSON, the President, occupying the chair, a discussion on

INSOMNIA

was opened by Dr. EUSTACE CALLENDER, whose address we publish on p. 1280.

Dr. GORDON HOLMES spoke on sleeplessness due to, or associated with, neurological conditions. The nature of sleep, he said, had been a matter of speculation and discussion since the time of the early Greeks; it had remained for Pavlov, by a series of brilliant researches, to bring the subject into the region of exact physiological investigation. His work was based on a study of the conditioned or acquired reflexes—i.e., special reactions to changes of surroundings—which Pavlov said were the reactions of new nervous connexions brought into existence in education and training. All these reflexes depended on the activity of the cerebral cortex. Under certain conditions the stimuli which at first evoked positive reflexes became inhibitory, arresting the active functions of the cortical cells concerned in the reflex; it was an active protective process, guarding the cells from functional derangement as a consequence of over-use or strain. It enabled the reflex centre to acquire localised sleep, and so recuperate. Repeated excitation at many cortical points might inhibit the whole cortex, unless kept in bounds by antagonistic nervous processes. This was in fact sleep, for sleep and internal inhibition were identical. In animals sleep was easiest induced by thermal and tactile stimuli. Moreover, a well-established rhythm in the succession of wakefulness and sleep might incite at predetermined periods the onset of sleep, apart from cortical fatigue.

Insomnia of neurological origin could be divided, he said, into the organic, the psychogenic, and the primary. Of these the least important was the organic, but insomnia as a primary symptom occurred in nervous disease, and the best instance was encephalitis lethargica. In that disease the sleep disturbance was almost certainly due to lesions in the region of the hypothalamus, or the grey matter around the floor of the third ventricle, where it was practically certain a "sleep centre" resided. Occasionally insomnia was a symptom in early general paralysis of the insane, especially during the restless and exuberant phase. In later stages lethargy was more usual. Sleeplessness was often, too, a prominent symptom in cerebral arterio-sclerosis, especially when associated with high blood pressure; usually it was found in the type characterised by mild headache, slight vertigo, and a rapid tiring by effort, with failure of mental concentration.

To the organic group belonged the sleeplessness due to certain poisons, such as alcohol or endogenous toxins. But it was in the functional or psychogenic nervous disorders that the neurologist most often me with severe insomnia. It was one of the commones symptoms in all forms of neurasthenia. Sometime such a patient slept for a sufficient number of hour but was not refreshed thereby. In the traumati variety, and in that due to emotional factors, slee was often disturbed by dreams. Sleeplessness migh also be a troublesome feature in hysteria, but here th complaint was apt to be exaggerated.

The most difficult forms of insomnia to treat wer those in the anxiety neuroses. Sometimes in sleeple persons no organic or psychogenic causal factor coul be discovered, and in some of these the inability t sleep enough seemed to be constitutional, ofte hereditary. In women of this type severe slee disturbances were liable to occur at the climacteric.

Treatment.

The cause of the sleeplessness should first be soug to be removed, but this was often a mere counsel perfection, as the insomnia had probably establishe a vicious circle. It was most important, especially the neuroses, to break the habit of sleeplessness quickly as possible. Often a few nights' good slee however obtained, restored the patient's confiden and established a mentality more favourable normal rest. Comfort and warmth could not neglected, and a change of surroundings was oft very beneficial. Most normal people slept best aft taking moderate exercise. In neurotic persons a bre from work and the substitution of open-air gam was of advantage. But there must not be overtire ness. Some patients, on the other hand, slept bett after a period of complete rest; this was especial so in the more exhausted types of neurasthenia, a in tired-out and poorly nourished people who we otherwise normal. Physical treatment could be great value in sleeplessness, and massage was the mo important of these, especially in exhausted state It was useful also when the symptom was associat with cerebral arterio-sclerosis. The masseuse mu be sympathetic, as annoyance might counteract t benefit. At first fairly vigorous, the massage shou become more gentle, and then the patient should made warm and comfortable for the night. excitable states massage was useless, and might disturbing. Hot baths late in the evening oft promoted sleep, though their effect might be to ma the patient more wakeful. In most cases the physici could not dispense with drugs, however much might wish to, and he thought the danger from th use had always been grossly exaggerated. The ri of abuse and prolonged administration was great in neurotics. Drugs were either sedatives or tr hypnotics. Of the former the bromides were the mo useful, especially in the treatment of the neuros Pavlov had shown that bromide in large doses quick cured fatigue and regulated the activity of the nerve system by strengthening the intensity of the inter inhibition. Larger doses of bromide should be giv than was the custom. If bromide alone would n induce sleep small doses of chloral could be add but only for a short time. Sometimes alcohol was sa and more effective than ordinary hypnotics, but on for those unaccustomed to its use. When a patie had difficulty in getting to sleep, but slept soun thereafter, medinal could be given, as it was quick absorbed. Wakefulness in the early hours called sulphonal, whilst light sleeping required bromid Several small doses were usually better than one la one. Taken all round, medinal was one of the m efficient of the hypnotics.

Sir MAURICE CRAIG agreed that lack of sleep w more damaging to the young than to the adult; a person with a psychopathic inheritance, or who w debilitated by illness or anxiety, might quickly beco confused if his sleep suddenly failed. He did propose to deal with the case of the insane; he w more attracted to the preventive aspect. Some peo must have their sleeplessness quickly relieved, serious changes would result. Generally the first th to do was to procure sleep for the patient.

deprecated, from the point of view of the patient and the public, the use of the term "sleeping draught." Except preparations like paraldehyde the drugs given were not really sleeping draughts, for they would not compel sleep if given in the daytime to a person going about his usual avocation. The term sleeping draught sometimes raised fears in the patient's mind, and might result in his refusal to use what was prescribed. Bromides, said Sir Maurice Craig, were very valuable in small doses, but if large doses were needed he regarded them as distinctly dangerous. It was not uncommon to find persons who were taking bromides in a confused mental state, the mind clearing when their administration was stopped; they also upset the digestion and were toxic to the skin. Paraldehyde was safe, but had great disadvantages in that its excretion took place through the respiratory tract, and hence the bronchial tubes were liable to be blocked by mucus, an important consideration in the aged. One of the most valuable sedatives was chloral, and Sir Maurice Craig preferred it to bromide. Five-grain doses could safely be given several times in 24 hours. He had never seen any ill-effects from the barbitone group, but he did not feel comfortable about prescribing sulphonal, save in quite small doses. He was against changing the hypnotic when he found one to suit the patient.

Sir WILLIAM WILLCOX thought insomnia should be approached from a general point of view, and that it was a mistake to begin treatment by resorting to drugs; general measures should first be given a good trial. The subject was very difficult, because of the variety of cases met with. In his experience the insomnia associated with delirium tremens and with choreic states would often yield better to a hot pack, or measures of that kind, than to drugs. In illnesses such as acute pneumonia, in which the toxins of the disease caused insomnia, it was necessary to secure sleep in the first few days before organs such as heart and kidneys were damaged by the toxæmia. For such cases, in the first three days, it was his custom to give hypodermically morphia, gr. $\frac{1}{8}$, and atropine, gr. 1/200, and when the struggle was reaching its height he left the patient to fight it out without running the risk of producing damage by hypnotic drugs. When, in neurasthenic and psychasthenic states, it was necessary to use hypnotic drugs, caution should always be observed, and their administration should not be long continued. It was the long continuance which was especially to be deprecated. And heroin seemed a particularly dangerous drug in this respect. He did not subscribe to the view that only unstable people became drug addicts; if heroin were given nightly for a month to members of a football team he believed half of them would become addicts. Many drugs produced a tolerance which was a danger. However valuable drugs might be for insomnia it must always be remembered that they were toxic. Bromural and adalin were valuable drugs, and he had not met with serious effects from them.

Dr. F. M. R. WALSHE said that apart from references to the great work of Pavlov almost the whole of this discussion might have taken place 30 years ago. The time had arrived when there should be a restatement of the problem of insomnia. Was the insomnia of anxiety neurosis, of nocturnal delirium, and of high blood pressure the same? Dr. Gordon Holmes's remarks contained the essence of the problem. Bromide was not a cerebral sedative, but an active stimulant. The information required about these drugs did not concern their toxic effects, but their normal pharmacological action. The problem needed re-orientation based on recent physiological knowledge.

Dr. ELLIS spoke especially of the difficulties of assimilation as contributing to sleeplessness. If something were given to empty the stomach between 3 and 4 A.M. the sleep broken at that time would often be restored, as, normally, the pylorus did not open during sleep.

Dr. C. P. SYMONDS said it had been pointed out that sleep was not invariably associated with low blood pressure and dilatation of the vessels of the limbs. In early psychoses it was difficult to distinguish between cause and effect. When a patient with anxiety neurosis was worried about his capacity to sleep it was well to give a hypnotic three nights in succession, telling the patient he could later on have a dose by his bedside to take in case of need. The knowledge that it was there generally enabled him to manage without it, as it banished his anxiety. He was a great believer in the efficacy of changing the patient's surroundings to break the wakeful habit.

Dr. GORDON LANE questioned whether sleep was ever so profound as to prevent the sleeper being aware of sound and other stimuli. When the blood was charged with waste products, which were probably doing much to keep up the stimulation which resulted in wakefulness, little good was likely to come of an intensive use of hypnotics.

TUBERCULOSIS SOCIETY.

AT a meeting of this Society, held on Nov. 18th, Sir STCLAIR THOMSON, the President, took the chair, and Dr. G. T. HEBERT read a paper on the

Treatment of Tuberculous Empyema by Replacement with Air.

He said that the tuberculous origin of an empyema, if not proved by the discovery of tubercle bacilli in the fluid, was inferred from the absence of secondary organisms in cases which gave evidence of old or recent tuberculosis in the corresponding lung. Tuberculous empyema, though an uncommon complication of pulmonary tuberculosis, was one which called for adequate treatment, because of the large quantity of fluid which collected—unless prevented by extensive pleural adhesions. The presence of a large volume of fluid, amounting sometimes even to 8 or 10 pints, not only collapsed the lung on the affected side, but also through displacement of the mediastinum compressed the already engorged lung on the sound side, causing dyspnœa and cyanosis. The fluid gradually increased in consistency and gave rise to a variable degree of toxæmia. If the condition remained untreated, the patient was liable to develop secondary infection, amyloid disease, or hypertrophic osteo-arthropathy.

The two main objects of treatment were: (1) to abolish toxæmia by removal of the fluid and by checking and preventing its reaccumulation; and (2) to relieve dyspnœa, by reducing the mediastinal displacement, thus allowing the lung on the healthy side to function normally, and by promoting healing of the pleura, which in time would allow of the partial expansion of the collapsed lung. The disadvantages of simple aspiration were mainly: (*a*) the distress caused to the patient by the removal of large quantities of fluid; (*b*) the difficulty of complete removal, this being also liable to cause sudden re-expansion of the lung; (*c*) reaccumulation of the fluid; (*d*) inadequate healing of the pleura. Rib resection was inadmissible, because of the grave risk of secondary infection. Gas replacement, on the other hand, repeated at intervals until the fluid ceased to accumulate, had many advantages. The pleural cavity could thereby be emptied almost completely; there was no marked change in intrapleural pressure, and no sudden displacement of the mediastinum; progress could readily be followed by X ray examination; the pleura was kept dry and consequently healed more readily, while any further deposition of fibrin was stopped; absorption of the gas in the intervals between replacements exerted an even and continuous traction on the diseased lung. Dr. Hebert believed that the results obtained by gas replacement were thus very much better than those obtainable by any other method. The patient was left with a respiratory capacity only slightly less than

normal, and recurrence of the empyema was impossible because the layers of the pleura were firmly adherent. The possible risk of reactivating pulmonary tuberculosis by expansion of the diseased lung in cases of tuberculous empyema was, he thought, more than counterbalanced by the prospect of almost complete restoration to health which was afforded by treatment by replacement.

Diagnosis could be made from the history and appearance of the patient associated with definite physical signs: fullness of the chest on the affected side, and relative immobility, especially of the lower part; absence of any resonance on percussion in this area; loss of breath sounds, of vocal resonance and of fremitus; and displacement of the mediastinum towards the opposite side. The nature of the fluid could, however, only be ascertained by exploration which should be undertaken in all cases of effusion.

With regard to the method of production, Dr. Hebert pointed out that tuberculous empyema could be produced in one of four ways: (1) from a simple serous effusion, the change usually taking place within a year from the onset of the effusion; (2) after spontaneous pneumothorax, this being looked upon by Fishberg and others as the commonest method of production; (3) as a complication of artificial pneumothorax, in which the serous effusion met with in about 50 per cent. of cases became purulent; and (4) from rupture of an abscess.

Dr. Hebert then gave details of 11 cases treated by gas replacement, in the majority of which an immediate improvement took place in the general condition of the patient, followed eventually by expansion of the lung and obliteration of the pleural cavity. In the remaining cases treatment had not been completed, but was progressing satisfactorily. In five cases the tuberculous pus was produced by the first method described above, in three cases by the second method, and in one case by the third. Two cases of hæmorrhagic effusion were included for comparison. In all these cases the fluid showed no secondary organisms either in the film or on culture. Tubercle bacilli were found in large numbers in the film in two cases.

Discussing the technique of the treatment, Dr. Hebert said that when an attempt was to be made to empty the pleural cavity a site should be chosen which would enable it to be tapped at its lowest point. For first replacements two needles were almost invariably used, the smallest size for withdrawing the fluid, and a Riviere refill needle, inserted higher up, for introducing the air from a Lillingston-Pearson type of pneumothorax apparatus. In subsequent replacements, however, when the amount of fluid to be withdrawn was about a pint, only one needle was used. The interval between replacements depended upon the rate of reaccumulation of the fluid, but it was probably wise to perform a replacement as soon as a pint had collected. In the average case the second replacement took place two weeks after the first, the interval being increased by one week for each subsequent replacement. As a rule, the number of replacements required was ten, extending over a period of about a year. Patients were well enough to return to work in about three months from the beginning of the treatment. Out of a total of nearly 90 replacements only one was followed by an abscess in the track of the needle, this being due to blocking of the needle by a long stringy clot which protruded from the wound when the needle was withdrawn. So far in his treatment of cases of tuberculous empyema there had been no need to resort to phrenic avulsion or thoracoplasty, and it was hoped to avoid these operations even in one of the cases cited in which the empyema was of seven years' duration.

Dr. Hebert emphasised the value of X ray examination in the management of the treatment. By this means it was possible at once to ascertain the degree of cardiac displacement, the state of collapse of the lung, the degree of completeness of replacements, the thickness of the pleura in some cases, the condition of the lung on the opposite side, and the presence of any cuplike adhesions which might hold some of the fluid.

A number of radiograms were shown, and the meeting ended with a short discussion.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON NOV. 22nd Prof. ARCHIBALD YOUNG read a paper on

Some Surgical Aspects of Gastric and Duodenal Ulcer.

He began by referring to a statistical study,[1] a his clinic, of the efficiency of modern methods o diagnosing ulcers of the stomach and duodenum, an of the value of gastro-jejunostomy in their treatment The diagnostic error had been found to be small, an to depend not upon any fault in the methods, bu upon erroneous deductions from the data which the provided. In that series 67 per cent. of patient had made a complete recovery after gastro jejunostomy, while 83 per cent. had been greatl or considerably improved. The operation done wa the usual posterior anastomosis, without pylori exclusion.

The new series upon which Prof. Young's presen paper was based included 146 definitely ascertaine cases, of which 12·3 per cent. were gastric, 28·08 pe cent. duodenal, and 59·6 per cent. pyloro-duodenal Of these, 122 had occurred in males, 24 in females. H believed that many pyloro-duodenal ulcers, althoug often classified as gastric, had more in common wit true duodenal ulcers than with those of the gastric type He still performed gastro-jejunostomy as an almos routine operation for peptic ulcer, and found i especially valuable in duodenal and pyloro-duodena cases. In his experience pneumonia was the chie cause of post-operative death; its incidence might b diminished by careful nursing, and—since the con dition was often of embolic origin—by gentleness i handling the ulcerated segment. The therapeuti effect of gastro-jejunostomy was due to a combinatio of factors, of which drainage and access to th stomach of the alkaline contents of the duodenu were important. It was unnecessary to occlude o divide the pylorus to ensure relief. Excision of th ulcer was generally valueless, unless combined wit some method of securing gastric drainage. Plasti operations at the pylorus were no more efficaciou than simple gastro-jejunostomy. Gastrectomy h reserved for large and adherent gastric ulcers, believin that so severe an operation was seldom justifiabl for more limited lesions. Partial gastrectomy did no eliminate, though it might lessen, the risk of recurrin ulceration. Post-operative jejunal ulcers were sai to occur in from 1–3 per cent. of cases, and amon the possible predisposing factors were high residua gastric acidity, unsuitable suture material, and loca infection. Prof. Young had so rarely encountere post-operative ulcer that he felt inclined to add geographical factor; he had not had a case in th series under review.

Much of the advance in the treatment of perforate ulcer was due, said Prof. Young, to Murphy, who ha consistently taught rapidity in operating and th minimum of interference. Gastro-jejunostomy wa rarely required either at the primary operation o later, as Nature was able to a considerable degree t correct the narrowing which might follow infoldin of the ulcer. Prof. Young preferred to drain the are of perforation locally. With regard to diagnosi most stress should be laid on a good history. Clinic and laboratory tests were of great help, but th interpretation of the results of X ray examinatio was very liable to error.

Reviews and Notices of Books.

SMALL-POX AND VACCINATION.

Handbuch der Pockenbekämpfung und Impfung. By Prof. Dr. OTTO LENTZ and Prof. Dr. H. A. GINS. Berlin: Richard Schoetz. 1927. Pp. viii.+900. With 108 illustrations in text and 7 coloured plates. M.50.

THIS large volume is a valuable compendium of past and present knowledge on the subject of small-pox and vaccination; its appearance is welcome at a time when in this country the occurrence of small-pox is increasing and the practice of vaccination is diminishing. The monograph contains 19 chapters, written by 16 different authorities, and opens with an historical section by Holländer, in which he relates the sources of the various kinds of vaccine lymph.

At the beginning of the nineteenth century vaccination proved a welcome and safe preventive against a severe form of small-pox. Later vaccine lymph, which had for years been passed from arm to arm, became so attenuated that only small and uncharacteristic vesicles resulted with uncertain protection. A return of vaccinia to the calf revived its activity and protective efficiency. Later still a weakening of calf lymph made necessary the attempt to renew the vaccine stock by inoculation of the calf with small-pox material, so as to start a fresh strain of vaccinia. This was eventually done, and incidentally established beyond doubt the essential unity of the two clinical conditions. The first recorded success in variolising cows was by Gassner about 1807 and later by Robert Ceeley in 1839. As illustrating the difficulty in carrying out this operation it may be recalled that Badcock in 1840, as the result of between 500 and 600 inoculations, succeeded on only 37 occasions in infecting cattle with variola. From them he obtained vaccine lymph which was extensively used. The serious difficulty found in infecting calves with small-pox directly led to the use of the monkey or the rabbit as a more susceptible intermediate host. These animals produce vaccinia which is active for man. Rabbits were first used by Calmette and Guérin in 1901 for testing and carrying on strains of vaccinia. The lymph known as "lapine" has proved a very useful and active seed lymph for the calf, which latter animal has remained the chief source of vaccine for human use. A new kind of vaccinia inoculum, known as neurovaccine, was introduced by Levaditi in 1923. It consists of the brains of rabbits inoculated intracerebrally with vaccine lymph. It is claimed by Levaditi that neurovaccine is of uniform and high activity, and does not contain any bacteria. The manufacture of lymph and recent experimental and strictly scientific inquiries are well summarised in the book.

A chapter by Gins deals with the objections to vaccination, especially to compulsory vaccination, which have been put forward at different times. The evidence for the high degree of protection against small-pox given by vaccination and revaccination is well set out, as is natural in a book coming from Germany, where these measures are very thoroughly carried out, and resulting freedom from variola is almost complete. The harmful effects which result from careless vaccination are dealt with at some length by Czerny and Opitz. The occasional occurrence of encephalitis after vaccination during the last few years is discussed, and the suggestion that the nervous disease is due to an added infection is held to be the most probable explanation.

In the section on pathology of variola and vaccinia special attention is drawn to the regular appearance of Guarnieri bodies in the rabbit's cornea following infection. These have been used as a means of diagnosing variola and of testing the strength of vaccinia according to the methods of Paul and of Gins. In the clinical and epidemiological accounts of small-pox the two different types of the disease are recognised. These are the oriental severe type, and the mild type now present in this country and known elsewhere—e.g., Peru, Australia, and Canada, and sometimes named alastrim. The identity of the virus in these two clinical forms is scarcely open to dispute, but its virulence and immunising properties show great differences in the two cases. When and in what circumstances the mild may revert to the severe form is quite unknown. The relations between animal and human pock diseases are dealt with, and the experimental evidence of cross immunity in this class of infections is discussed. The existence of any community of virus between vaccinia and fowl-pox is not accepted. On the other hand, that the same virus may be, and in many cases is, responsible for small-pox and vaccinia in man and monkeys, and for cow-pox, sheep-pox, goat-pox, horse-pox, and swine-pox is agreed to as proven. The immunity to vaccinia and small-pox is in part, at any rate, humoral, and due to antibodies which can be found free in the blood, but the existence of an additional "tissue" immunity in the skin is considered possible but not, so far, satisfactorily demonstrated.

A careful summary is given of the observations on the wide distribution of vaccinia virus in the body of vaccinated animals which has been shown to exist by Ishigama, Blaxall, Ohtawara, and others. The histology of variola and vaccinia are dealt with, and the view taken by Paschen, Prowazek, and Levaditi, that in vaccinia the seat of the primary pathological process and the multiplication of the virus is in ectodermal cells, is recorded, but Ledingham's recent evidence pointing to the infection being essentially in the reticulo-endothelial system is not quoted. The various attempts and failures to cultivate the virus in ordinary media are narrated, and the work of Parker and Nye, in which they appear to have propagated it in cultures of testicular tissue, is spoken of as hopeful. The more recent demonstration of remarkable increase of vaccinia virus in cultures of embryonic chicken tissues had evidently not been published early enough for inclusion in this article.

In conclusion it may be said that this book is a most useful and judicious summary of knowledge on the whole range of its subject matter. References to the literature are adequate, even if placed rather awkwardly at the end of each chapter and not in a general index of authors. There is, however, a general subject index at the end of the book.

THE ENDOCRINES IN GENERAL MEDICINE.

By W. LANGDON BROWN, M.D., F.R.C.P. Lond., Physician to St. Bartholomew's Hospital. London: Constable and Co. 1927. Pp. 144. 7*s.* 6*d.*

THIS little book forms one of the Modern Medical Monographs series, edited by Prof. H. MacLean, and is written primarily for the general practitioner, who will find in it an account of the endocrine system and its diseases presented in a form which should certainly be of service to him. The system is here treated as a whole rather than as a number of isolated units; there are chapters, for instance, on the biology of the group, behaviour in childhood, effects on general metabolism, and relationship to the psychoneuroses. This method of presentation differs from that of most other text-books on the subject, and the outlook is welcome. There are, however, other chapters devoted to the more important individual glands and their diseases, notably the thyroid, the parathyroids, the pituitary body, and the adrenals. In these sections Dr. Langdon Brown has drawn largely from his own personal experience, both in the laboratory and at the bedside. Useful information is given with regard to recent methods of investigation of these syndromes and their treatment, and the observations of other clinicians and laboratory workers, where they have a practical application, have been incorporated in the text.

There is a final chapter on endocrine therapy, which is necessarily cautious in tone. It is pointed

out that therapy has not kept pace with the increase in our knowledge of the endocrine system. In one sense this has been as well; for the way in which glandular and other extracts have often been ignorantly given in the past would inevitably have done harm had they been potent. Fortunately, the majority were not. At the present moment Dr. Langdon Brown considers that reliance can safely be placed on thyroid and pituitary medication. Insulin has, of course, already proved its worth. Collip's parathyroid extract is a new preparation, which is of great value in tetany due to parathyroid deficiency, and the ovarian extract of Allen and Doisy, which is now available for general use, promises, when its effects have been more fully investigated, to be of considerable practical utility. Adrenalin, the secretion of the adrenal medulla, is well known to produce beneficial effects in certain diseases, notably asthma. Its limitations in Addison's disease are fully discussed. Dr. Langdon Brown is frankly sceptical as to the value of extracts of the adrenal cortex, and he has never seen definite results follow the administration of extracts of thymus, pineal, prostate, placenta, or mammary gland. The therapeutic use of endocrine preparations is much in need of such a well-considered and authoritative opinion, which strikes a judicious mean between that of uncritical and over-enthusiastic endocrinologists and the cautious, if not agnostic, physiologist.

CLINICAL NEUROLOGY.

For Practitioners and Students of Medicine and Medical Students (a free translation, with changes and additions, of the book by Prof. H. Curschmann, Rostock). By EDWARD A. STRECKER, A.M., M.D., Professor of Nervous and Mental Diseases, Jefferson Medical College, Philadelphia; and MILTON K. MYERS, B.S., M.S., Neurologist to the Philadelphia Northern Liberties Hospital. Philadelphia: P. Blakiston's Son and Co. 1927. Pp. 410.

A BOOK of this kind is apt to prove unsatisfactory, however laudable the motives of its authors. Believing, as they appear to do, that "there exists a real need for a brief clinical exposition of neurology," they have thought of supplying it by furnishing the student with a "boil-down" of a German text-book conceived on considerably more ambitious lines. No illustrations or diagrams relieve its pages, though neat little paragraphs, enclosed within rules, head sections on different diseases and contain snappy summaries quite in the best medical journalese. Life is too short, apparently, and medical art too long, to refer to well-known signs except as "Romberg," "Babinski," and so forth. If the general teaching of the book is accurate enough it scarcely compensates for a condensed brevity resulting in such erroneous statements as: "Epilepsy is a dreadful disease;" for epilepsy is not a disease and in innumerable instances its manifestations are benign.

POSTENCEPHALITIC RESPIRATORY DISORDERS.

By SMITH ELY JELLIFFE, M.D., Ph.D. New York and Washington: Nervous and Mental Disease Publishing Company. 1927. Pp. 135.

OF the various menacing and therapeutically embarrassing sequelæ of epidemic encephalitis an unenviable place must be given to disorders of the respiratory apparatus, because of their complexity, frequency, and intractability. Dr. Jelliffe has performed a useful task in collecting and collating a large number of recorded cases and in adding personal cases in considerable detail. With so much material problems of classification and physiological grouping can receive a more satisfactory solution than is possible for the student of isolated examples. Nothing is clearer than that implication of more than merely one functional level is responsible for the clinical varieties of this respiratory affection. In some cases bulbar, in others pontine, mesencephalic, thalamic, cortical mechanisms can be demonstrated to be playing a part. The author goes further, holding that in other examples the trouble has a psychopathological basis, and evidently favours such views as that it may be a representation of a "larvated masturbation," that some of the phenomena are "loosened bits of anal-erotic functioning," and what not. Of discussions of this kind the general remark may be made, that they confirm the believer in his belief but leave the sceptic sceptical.

ANATOMY OF THE NERVOUS SYSTEM.

Anatomie élémentaire des centres nerveux et du sympathique; vie de relation et vie végétative. By P. GILIS, Professor of Anatomy in the Faculty of Medicine of Montpellier. Paris: Masson et Cie. 1927. With 35 diagrams and one plate. Pp. 225. Fr. 20.

THAT books on the anatomy of the nervous system continue to appear is doubtless all to the good, if it stands for recognition of the necessity of a knowledge of neuro-anatomy as a basis for any further study of that system. Certainly the student has a far wider choice in this respect than his predecessors of 20 or 30 years ago. Prof. Gilis's little manual deals with the matter from a physiological viewpoint mainly, in that only the broader lines are drawn in the picture, while histological details are omitted and throughout its pages the correlation of function with structure is carefully sketched. The diagrams reach a high standard of clearness and seem to be remarkably accurate, on the whole. In Fig. 14, however, we consider the vestibulo-spinal tract is assigned a position in the cord that is rather too lateral, and this would appear to be the case also with Helweg's tract. That tectospinal and reticulospinal tracts should be omitted is doubtless an oversight. In Fig. 10 the apparent origin of the twelfth nerve is placed at a somewhat higher level than that usually given for it. The sections dealing with the sympathetic system are unusually full and the relations of its parts are clearly expressed. With this unambitious manual for a guide the student should find the way smoothed for him when he begins his acquaintance with the nervous system.

The Anatomy of the Nervous System, from the Standpoint of Development and Function. Third edition, revised. By S. W. RANSON, M.D., Ph.D., Professor of Neuroanatomy, Washington University School of Medicine. London and Philadelphia: W. B. Saunders Co. With 284 illustrations, some in colours. 1927. Pp. 425. 32s. 6d.

THE third edition of Prof. Ranson's text-book of nervous anatomy is little altered from its predecessors. New material incorporated deals with recent advances in knowledge of neuroglia and its varieties. Revision has been carefully carried out, in accordance with newer conceptions of organisation and function of the nervous system. In its present form the book provides a useful foundation in macroscopical and microscopical anatomy, considered always with an eye to the physiological correlates of given structures, thus supplying a dynamic as opposed to a static presentation. With clear diagrams and with numerous bibliographical references it is wonderfully complete, and for the novice in neurology it should prove highly serviceable.

SAFEGUARDING OF INDUSTRIES.—The question of renewing Exemption Orders Nos. 1, 2, 3 and 4, which are due to expire on March 6th, 1928, is now under consideration of the Board of Trade. The articles covered by these exemption orders include barbitone, dial, didial, guaiacol carbonate, hydroquinone, methyl sulphonal, phenacetin, phenazone, piperazine, pyramidon-veronal, salol, sulphonal and urea. Communications should be addressed, before Jan. 8th, to the Principal Assistant Secretary, Industries and Manufactures Department, Board of Trade, Great George street, Westminster, S.W. 1.

THE LANCET.

LONDON: SATURDAY, DECEMBER 17, 1927.

SLEEP.

THE general public, while taking normal sleep very much for granted, has always been ready to marvel at pathological states of somnolence. The trance, whether hysterical or induced by hypnotic suggestion, frequently attracts the attention of the daily newspaper, and the prominence of lethargy among the symptoms of epidemic encephalitis speedily gained for that disease a widespread notoriety. Until the present century neither physiologists nor physicians have been able to offer the layman much enlightenment as to the nature either of normal sleep or of its pathology, though there has been no lack of theories, as was shown by Dr. E. M. CALLENDER in his recent address to the Medical Society of London (published on p. 1280), and in the subsequent discussion (p. 1294). Recently, however, as in the case of numerous phenomena, converging lines of research, many of which had at first no apparent relationship to sleep, have led to a focus of illumination, in the light of which a definite conception of the nature of sleep is already becoming outlined. The most unexpected of these contributions to our knowledge has been the outcome of PAVLOV'S investigation of conditioned reflexes. PAVLOV found that in the course of experiments on the conditioned reflexes of dogs the animals often unaccountably fell asleep. He was able to relate this phenomenon to the presentation of stimuli which had been endowed with inhibitory effects. This led him to adopt the view that sleep and inhibition were identical. An inhibitory process initiated at some point in the cerebral cortex by an appropriate stimulus tends to spread over the whole cortex and the animal falls asleep. According to PAVLOV, we may with equal truth describe sleep as generalised inhibition or inhibition as localised sleep. How is this conception to be brought into relation with the capacity of certain drugs for producing sleep? The first step in this direction was taken by PAVLOV himself, who showed that inhibitory conditioned reflexes were greatly strengthened by the administration of bromides, while the reverse effect was produced by caffeine. PAVLOV'S conception of sleep as inhibition is thus supported by the fact that drugs which enhance inhibition also produce sleep, while the reduction of inhibitions and wakefuiness are similarly affected. HIRSCHFELDER and SERLES have shown that the large group of anæsthetic and hypnotic drugs, in spite of their chemical diversity, possess an important physico-chemical property in common. When added to an emulsion of oil and water they convert the oil-in-water phase of the emulsion into the water-in-oil phase. The effect of this is greatly to raise the electrical resistance of the emulsion. It seems a justifiable hypothesis that these drugs act in the same way in the body and that by altering the phase of the emulsion of lipoids which constitutes the cell membrane of the neurons they reduce electrical conductivity in the nervous system, possibly at the synapses. Whatever be the correct view as to the physiological nature of inhibition, it seems necessary to believe that inhibited neurons are maintained in a distinctive physico-chemical state which renders them refractory to stimuli reaching them. Thus it may well be that in physico-chemical terms there is no difference between inhibition and sleep. This, however, does not mean, as PAVLOV seems rather to imply, that sleep and inhibition are interchangeable terms, for its localised character is of the essence of inhibition, whilst a general reduction of activity is equally characteristic of sleep. The distinction between them therefore remains of great physiological and psychological importance.

Nevertheless the recognition of a relationship between sleep and inhibition illuminates many aspects of sleep and allied states. In PAVLOV'S experiments sleep was a conditioned reflex—that is, it was capable of evocation through a process of association by many stimuli. Even painful stimuli could in this way become effective in causing sleep. So in everyday life the act of undressing and retiring to bed, darkness, and muscular relaxation are conditioned stimuli which reflexly evoke normal sleep. For this reason many people experience some difficulty in going to sleep for the first time in a strange room, where some of their usual stimuli are absent. Further, sleep, like inhibition, can itself be reflexly inhibited, and a succession of sleepless nights may, to use a mathematical term, change the sign of the familiar stimuli so that by association they now evoke not sleep but wakefulness. This explains the value of the early use of sedative drugs in the treatment of insomnia. The drug produces sleep by acting at the physico-chemical level, but by so doing it breaks the conditioned inhibition of sleep which has grown up, and re-establishes the normal response to the ritual of retirement. It seems likely that both the hypnotic trance and its associated state of suggestibility are to be explained on the basis of PAVLOV'S conception. On this hypothesis hypnosis would seem to be a condition intermediate between physiological inhibition and full sleep. Rapport with the hypnotist is a thread of wakefulness uniting the subject to the external world, but the diffuse inhibition of his judgment and self-assertive impulses compels an uncritical acceptance of the suggestions made to him. The late S. R. WILSON, whose recent death robbed the profession of a brilliant investigator, found that by causing a subject to inhale a mixture of nitrous oxide and oxygen he could produce a state of greatly enhanced suggestibility without loss of consciousness, and he attributed this effect to depression of the highest mental functions. He found also that caffeine in a similar way enhanced suggestibility, a fact which may afford a physiological basis for the destructive effect of tea-table gossip upon reputations.

Whereas physiology and pharmacology support the view that sleep is a function of the whole cerebral cortex, pathology appears in some measure to favour the hypothesis of the existence of a sleep "centre." The lethargy of encephalitis usually resembles normal sleep in that the patient can be aroused, and its constancy as a symptom of that disease would seem to be related to the predilection of the virus of encephalitis for the mid-brain and hypothalamus. It is well known that somnolence is often a symptom of tumours and abscesses in this region. On these grounds it has been suggested that the thalamus operates as a sleep "centre" by cutting off from the cortex the stream of sensory impulses. This view seems hardly tenable, for a lesion which produced lethargy in this way could scarcely fail to cause sufficient impairment of sensibility to be discovered by examination, and this is conspicuously rare in encephalitis. A possible clue to the problem is afforded by the remarkable condition known as

narcolepsy which is characterised by sudden, brief, and irresistible attacks of sleep. Narcolepsy is often unaccompanied by any evidence of disordered metabolism, but in some cases, as in the famous fat boy in Pickwick, it is associated with obesity. We are now coming to attribute many so-called symptoms of "hypopituitarism" to lesions of the hypothalamus, and there is a large body of evidence that important metabolic centres are located in this region. It seems not unlikely that changes in cerebral metabolism may play a part in the production of pathological and indeed normal sleep, and that the sleep centre which may be affected by disease is a centre which regulates the metabolic activities of the nervous system. If this were so, the physico-chemical basis of sleep would form a bridge between PAVLOV'S theory and the hypothesis of the existence of a sleep centre.

HUMAN TRYPANOSOMIASIS IN AFRICA.

IN vast regions of the tropics there is dispute to the death between man and insect, and in Africa sleeping sickness gives urgent proof that man as yet hardly holds his own in the continuing struggle. The Interim Report[1] of the League of Nations' International Commission on Human Trypanosomiasis in Africa is of special interest because the outlook of such a band of investigators is not limited by local conditions. Though much valuable work has been, and is being, done in various countries, the problems of trypanosomiasis remaining to be solved are of fundamental importance for control of the disease, and perhaps, as the Commission suggests, it is less likely to yield its secrets to isolated observers than to steady coördinate research. Already the Commission is convinced that the biology of the human trypanosomes must be studied in man himself, and in strains freshly isolated from man, and that the work can be carried out only within reasonable distance of the naturally infected areas. Since different areas are suited to different lines of inquiry, there has in the past been a tendency to local specialisation; thus, while the clinical and therapeutic studies made in the Belgian and French Congo show what can be done with abundant clinical material, nothing is yet known about the transmissibility, and little about the detailed morphology, of the Congo strains of human trypanosomes. In Uganda, where circumstances have not helped extensive clinical inquiry, most of the research has concerned the parasite's behaviour in the insect vector; whilst in other countries efforts have been directed mainly to control and eradication. The Commission points out that though this topographical specialisation is natural, and has certainly not been fruitless, there is undoubted need for freer exchange of results and ideas between the widely separated workers, for standardisation of technique, and even for "judicious" combination of methods to be applied in all infected areas. Thus would be gathered a mass of accurate information on which important conclusions could be securely based.

The present investigations have been carried out in the Kavirondo district by Lake Victoria Nyanza, and personal reports are submitted by various of the Commission's members, all of whom had previously made distinguished contributions to our knowledge of human trypanosomiasis in the African field. Prof. F. K. KLEINE finds that in the Kavirondo district there is at present no epidemic of sleeping sickness—a fact which is due rather to the small percentage of infected tsetse than to any immunity in the population. He also records the discovery of the famous posterior nuclear forms in *Trypanosoma gambiense* which shows that these are not, as was supposed, peculiar to *T. rhodesiense*. Dr. G. LAVIER contributes a study of the development of posterior nuclear forms, and states that in man *T. gambiense* may take on an appearance identical with that of *T. vivax*. This makes it doubtful whether the latter is a human parasite. Dr. LYNDHURST DUKE shows that the resistance of a trypanosome to arsenic persists after cyclical passage of the strain through the tsetse, which has a bearing on the use of atoxyl as prophylactic against human trypanosomiasis. And a strain resistant to arsenic may be resistant to antimony. He has found also that inhibition by *Glossina palpalis* of the blood of monkeys treated with Bayer 205 does not inhibit development in the tsetse of *T. gambiense*. Bayer 205 protected a monkey against infection by cyclically infected tsetse for not more than two months. Dr. L. VAN HOOF has discovered nothing to suggest the existence of any reservoir of the virus other than man (a statement which receives recent confirmation in important observations by Dr. W. H. DYE in South-East Tanganyika Territory),[2] and that there is no carrier besides glossina. The trypanosomes are transmitted cyclically; if transmission were mechanical it would lead to the formation of limited epidemic foci. Examination of the cerebro-spinal fluid is, he says, really necessary in infected cases, and the degree of change in the fluid indicates the virulence of the trypanosome and the stage reached by the disease. Dr. VAN HOOF holds that differences in gravity of the disease are due to variations in virulence of the trypanosome rather than to any character in the patient which could be explained as immunity or tolerance. The spread of the disease is favoured by occupation—especially fishing. Famine often leads to abandonment of agriculture for fishing and so to exposure to tsetses, though it must be gravely noted that the tsetse can be found in banana groves adjoining villages. Endemicity depends on occupation, and security is gained only by complete separation of hosts from trypanosomes; the virus, however, becomes weakened in endemic areas if no new trypanosomes, flies, or men be introduced. It is noted that sensitiveness to arsenical drugs varies greatly in different endemic areas, and in the same area, and evidently this variation must be reckoned with in judging of the therapeutic value of any drug.

The International Commission has gathered much other information not yet ready for publication, and has opened up a vista of research extending far beyond the term set to its continuance as a working unit. Though it may not be possible or desirable to fulfil its apparent wish to control all investigation in sleeping sickness areas, there can, nevertheless, be no doubt of the wisdom of its appointment and the value of its work.

BURIAL AND PUBLIC HEALTH.

WHEN making improvements last year in the law of coroners' inquests and death registration, Parliament took the opportunity to provide for another and by no means unimportant aspect of the disposal of the dead. Section 9 of the Births and Deaths Registration Act of 1926 enacts that the Minister

[1] Published by the League of Nations Health Organisation, Geneva, 1927. Obtainable in London from Messrs. Constable and Co.

[2] W. H. Dye: Trans. Roy. Soc. Trop. Med. and Hygiene, November, 1927, xxi., No. 3.

Health, with the concurrence of the Home Office, may make such regulations "as to the period of time a body may be retained after death in an inhabited house or other premises," as may be deemed desirable in the interests of public health. No such regulations have yet been made; it is believed that the making of them is under consideration, and it will be agreed that some such action is desirable. It is by no means unknown for a body to be kept eight or ten days after death in a small room in a crowded house. An instance, for example, is reported in which, after the deceased had died in hospital from an operation, the body was removed and carried with difficulty (and not without bruising) up narrow stairs to a room at the top of a tenement building, there to remain for as much as eight days and to be exhibited to all and sundry who from various motives had the desire to look upon a corpse. Sometimes, it may be, the reason for the delay in burial is that undertakers have difficulty in carrying out the interment earlier; more often, no doubt, the explanation is to be found in some traditional or perhaps morbid instinct which is at variance with modern standards of public health. It is a little surprising that our progressive municipalities, whose local legislation has so often set an example to the country at large, have not provided more definitely for the removal of dead bodies from dwelling-houses within a fixed period after death. Medical officers of health must often be aware of the desirability of some such provision.

Pending the making of regulations under the 1926 Act already mentioned, the existing law gives little help. The subject of burial was anciently—and for a time exclusively—a branch of the ecclesiastical or canon law. In more modern times there have been elaborate judicial utterances which have contained miniature treatises on particular aspects of burial. Such was Lord STOWELL'S judgment in Gilbert *v.* Buzzard in 1820, the case of the iron coffins. Such also was Mr. Justice STEPHEN'S charge to the grand jury at Cardiff in 1884 in Rex *v.* Price, setting out the legal attitude towards cremation, the accused having indicted for attempting to burn a child's body to avoid an inquest. The use of corpses for dissection and anatomical study was another occasion for judicial exposition. Out of all these instances the rule is to be deduced that the law presumes that everyone will wish that the bodies of those in whom he was interested when they were alive shall have Christian burial; the law declines to entertain the possibility that any other view would be contemplated. The Christian has a right to a decent funeral. The individual, it was said in Rex *v.* Stewart in 1840, under whose roof a poor person dies, is bound—if no one else has the duty—to carry the body decently covered to the place of burial; "he cannot keep him unburied . . . he cannot cast off the body so as to expose it to violation or so as to offend the feelings or endanger the health of the living." Similarly in Rex *v.* Vann, 11 years later, it was laid down that a man must give Christian burial to his dead child if he has the means of doing so; if he fails in this duty, he can be indicted for a nuisance at common law—i.e., for doing something which affects the public health, comfort, and safety; but, at the same time, he cannot be convicted and punished if he cannot afford to pay for the burial.

Such is the existing law and, though its basis is sound, it is inappropriate as a remedy to-day. The cumbrous machinery of the law of nuisance is not what is required; the neighbours in a tenement building are not likely to consult their solicitors to set that machinery in motion. We require some simple regulation which will insist that bodies are removed from dwelling-houses within a fixed period after death just as at present a local enactment can insist on the removal from a dwelling-house of a person suffering from infectious disease. The motive of public health is the same in each case. It will be necessary to provide for the accommodation of the body in the interval, if any, before burial. The mortuary is perhaps too strongly associated in the public mind with murders, suicides, and the casual tragedies of the streets or the river. In this matter of the disposal of the dead there is need to educate the public, even at the risk of interfering with the manifestation of feelings in which natural affection, religion, and custom all have part. In this task of education many can help—clergy, medical officers and practitioners, health visitors, and undertakers; their services must be mobilised in support of any action which the Ministry of Health may take.

Annotations.

"Ne quid nimis."

THE JUVENILE DELINQUENT.

Dr. Hamilton-Pearson's paper on child delinquency, which we publish on p. 1312, should be of interest to all social workers and medical practitioners. There are many who recognise the urgency of the problem, but do not know the possibilities of treatment as compared with punishment; there are others who tend to turn down all general recommendations as impracticable. That Dr. Hamilton-Pearson's approach to the subject is broad-minded they will see from his description of a group of cases in which punishment of some kind is recommended in addition to medical treatment. It should be made clear at the outset that the figures do not relate to a series of cases of delinquency as they occurred, but to a special group of cases considered serious, or suitable for medical treatment, and therefore referred for medical examination. Although it may be at first impossible to study all the young people for whom medical and psychological investigation is desirable, it is clear that the harvest of hopeless criminals will gradually diminish if even a moderate number of delinquents are properly looked after. Such enlightened care will serve as an object-lesson to magistrates, probation officers, and the general public, so that the children will be investigated at an earlier and more hopeful stage. Dr. Hamilton-Pearson's paper indicates not only methods of treatment but also possibilities of prevention, and when school clinics are able to deal with psychological as well as physical disabilities, and are in closer touch with parents and with those who deal specially with delinquents, prevention will be no idle dream; though the school clinic will never reach its fullest usefulness until the infant welfare clinic has had similar possibilities in view. This is no more than to say that some skilful person should keep a watchful eye on every child from an early age. Ideally this should be the family doctor, and many practitioners already have sufficient knowledge, combined with sympathy and common-sense, to deal with these difficult problems. Only a small proportion of young delinquents who find their way into prison are mentally defective within the meaning of the Mental Deficiency Act. At a conference reported in THE LANCET last week (p. 1255), Dr. J. J. Landers, Governor of H.M. Prison for Boys, Wandsworth, put the figure at 5 per cent., pointing out that many of the others are below the average in intelligence, whilst many are physically defective. His high tribute in this connexion to the work of the special schools is well deserved, though other agencies are responsible in part for the good results obtained. If further evidence is needed in favour of more individual treatment of children recognised at school as potential delinquents, it may be found in contributions to a discussion[1] at the annual session of the American Medical Association at Washington in May of this year, where similar conclusions were drawn and similar proposals made. In conclusion, we may refer to the suggestion that it is unwise to appoint magistrates partly as a reward for services in other walks of life. It is arguable that if such an

[1] Jour. Amer. Med. Assoc., Nov. 5th.

appointment is to be looked upon as a reward at all it should come as recognition of success in social work of some kind, and at the Ninth International Prison Congress, held in London in 1925, it was recommended that "all who wish to be magistrates should be compelled to attend lectures on psychology, sociology, forensic psychiatry, and penology." That this argument should be put forward is symptomatic of a gradual change in the functions of justices of the peace, who are nowadays expected to work in with a variety of social organisations, charitable and otherwise. The right use of their powers is becoming more and more difficult, and requires increasing knowledge of the means by which difficulties can be best resolved and abnormalities corrected. On the other hand, there are objections to making the bench primarily into a body of experts, and to do so is contrary to the English tradition by which the expert is generally used as an adviser.

SACRO-ILIAC SUBLUXATION.

THE sacro-iliac joint has not received as much attention in Europe as it has in America, where in some circles slight changes in it are credited with causing troublesome symptoms. The Boston school of orthopædic surgeons, and notably J. E. Goldthwait, have been leaders in the study of the joint and its abnormalities, but the latest study of sacro-iliac subluxation as a cause of backache comes from Chicago. In an article in *Surgery, Gynecology, and Obstetrics* for November, Dr. H. Hoyt Cox gives a useful summary of the history of the subject and of the methods of treatment hitherto recommended and practised. These methods consist of manipulation, rest, and the application of adhesive strapping or pelvic corsets, whilst for the more severe cases ankylosing operations on the joint, by means of bone-grafts and removal of cartilage, have been employed. The diagnosis of sacro-iliac subluxation or relaxation seems to be commonly made in America, although it is rare for the condition to be demonstrated anatomically, and as a rule this can only be done in the course of an operation for its relief; X rays are of little or no use in this connexion. Dr. Cox gives statistics of 80 cases under his own care. Of these, 50 "acute" cases were completely and permanently relieved by manipulation, strapping, and one week's rest in bed. Thirteen were completely relieved but relapsed. Of the remaining 17, of which only two were "acute," nearly all were relieved by treatment. None of the 80 cases was submitted to any cutting operation.

A study of such statistics and descriptions, and of those published by Goldthwait and his school, must lead to reflection on the apparent disproportion between the means of treatment adopted and the important and massive structures concerned. It is very hard to see how adhesive strapping, no matter how tightly applied to the skin, can exert any serious control over the sacro-iliac joint, even though it encircles the whole pelvis. Nor can we expect a spinal support or pelvic corset to be any more effective. The joint can no doubt be fixed—if fixation is desirable—by the bone-grafting operations of Albee, Smith-Petersen, or Verrall, but Dr. Cox's cases, and most of the others published, were cured with astonishing rapidity, without recourse to any severe measures of this kind. Abnormal mobility of this joint and obvious alteration of the parts composing it have rarely been noted, and subluxation but rarely diagnosed, in this country; yet we hesitate to conclude that the anatomical peculiarities and way of life of the citizens of the United States differ so greatly from those of the inhabitants of Great Britain as to account for the discrepancy. Moreover, it is not in this country only that doubt is entertained of the frequency of the lesion. Dr. Royal Whitman, of New York, writes on the subject with great caution in the lately published eighth edition of his "Orthopædic Surgery," and although he describes operations for the relief of the so-called subluxation, he quotes no experience of his own. Sir Robert Jones and Dr. R. W. Lovett of Boston, in their standard work published in 1923 were more outspoken sceptics. They wrote: "One of the writers has never seen a case of this type where he was able to detect abnormal mobility, although he has seen a great number of cases where there was direct tenderness over the sacro-iliac joint, much relieved by wearing a belt. The other writer has seen two cases where he believed a slight displacement of the sacro-iliac joint existed." These discrepancies in the experiences of surgeons of wide reputation and proved diagnostic skill are very puzzling. It is not merely a difference of opinion between American on the one hand and Europeans on the other, for as we have shown, two of the very foremost orthopædic surgeons of the United States have failed to encounter more than a few such cases, whereas one surgeon in Chicago has already treated 80. An international discussion on this subject might be enlightening.

VITAMIN CONTENT OF HUMAN MILK.

IN a series of papers in the *Journal of Biological Chemistry*[1] Icie G. Macy and her co-workers describe an investigation into the vitamin content of human milk. They were lucky in having at their disposal an apparently unlimited supply provided by the Detroit Wet Nursing Bureau. The milk was usually a sample from the pooled yield of 10–16 mothers in various stages of lactation, so that the difficulties often arising from the use of a non-representative supply were avoided. The women were receiving an average American dietary, and the results may therefore be regarded as pretty widely applicable. Thus far the vitamin A and vitamin B value of the milk has been examined. Before this work very few biological tests of the vitamin value of human milk seem to have been made, though inferences have often been drawn from the clinical condition of infants. Macy quotes C. Kennedy[2] and co-workers, who showed that breast-milk may vary very greatly in its vitamin A content, according to the diet of the mother. E. M. Hume,[3] working in Vienna, showed how in some cases consumption of cod-liver oil by the nursing mother may completely alter the vitamin content of her milk, whilst in others there appears to be no change. The latter cases she explained as being ones in which the mother's own body was so depleted that the vitamin was retained instead of being passed on to the baby; one mother, for instance, who received cod-liver oil and extra feeding for two months put on 43 lb. in weight without any change in the vitamin content of her milk. On the whole, however, it appears that in human beings, as in other mammals, there is a direct connexion between the diet of the mother and the amount of vitamin in her milk. Macy and her co-workers found that the value for vitamin A of human milk from the wet nursing bureau did not differ greatly from that of the milk of cows which were allowed alfalfa hay and ensilage with cereals, but no pasture. The milk was tested not only by the growth of rats but also by their power to reproduce and rear their young, and the interesting observation was made that a certain daily ration of vitamin A may be enough for a mother rat to grow, reproduce, and lactate, but that when her offspring are tested on a diet deficient in vitamin A, they may quickly show that they have little or no reserve. This observation is instructive and teaches a valuable lesson. In regard to vitamin B, Macy and her co-workers did not get so clear-cut a result, nor is it quite certain with which fraction of vitamin B they were dealing; probably it was with the anti-neuritic fraction. They concluded that "the anti-neuritic potency of mixed human milk, at least from a group of women

[1] I. G. Macy, J. Outhouse, M. L. Long, and A. Graham. Jour. Biol. Chem., 1927, lxxiii., 153, 175, 189, and 203.

[3] E. M. Hume: Med. Res. Counc., Special Report Ser. No. 77, 1923, p. 153.

eceiving the average American dietary, is very light," and further, that "it is possible that many nothers do not supply enough of vitamin B to their abies." If this conclusion is true in England, it can nly be true in the sense that there exists a partial r latent deficiency, because the expression of a more evere degree of deficiency is the development of nfantile beri-beri, as we know by reference to the hilippine Islands. There Andrews[4] made the classical xperiment of feeding puppies on the milk of human nothers, whose infants had died of beri-beri; within hree or four weeks the puppies all showed symptoms ke those of beri-beri and ultimately died. Whether condition of partial deficiency in vitamin B can be ostulated amongst a population, such as the English, here the expression of the full deficiency is never en, seems a little doubtful, but in view of opinions hich have been expressed as to the possible insufficiency of vitamin B in the general diet of this country, is interesting to find that there is experimental idence for its existence in America.

A HEALTH SURVEY IN ILLINOIS.

THE Illinois State Department of Public Health s issued the story of its health activities over a riod of 50 years in a substantial book with the le "Rise and Fall of Disease in Illinois." In the eface the Governor of the State puts forward asons why the triumph of man over disease in inois ought to interest every person in the State; report itself, presented by Dr. Isaac Rawlings and colleagues, Dr. W. A. Evans, Dr. G. Koehler, and . B. K. Richardson should offer no difficulty to intelligent layman. Of more than local interest the relatively long list of "biologics" distributed e of charge, apparently from 1922 onwards; in dition to diphtheria antitoxin and small-pox ccine, the list includes diphtheria toxin and toxinitoxin, typhoid vaccine, and silver nitrate solution the prophylaxis of ophthalmia neonatorum. Atirabic vaccine is given free to poor people only. the use of toxin-antitoxin is ascribed the decline the death-rate from diphtheria from 22·2 per 0,000 in 1921 to 5·7 in 1926. Antityphoid vaccina, advocated since 1911, was largely used for phylaxis during the flooding of populated areas in thern Illinois in 1925. Field laboratories were ituted for use in outbreaks in out-of-the-way as; they have also been used for the diagnosis glanders and venereal disease, milk bacteriology, general laboratory work. Up to 1915 a monthly etin was published for a medical audience, since it has been popular in character; the Division Public Health Instruction possesses a motionure library containing some 80 films for uitous loan throughout the State. The report s with some matters of historical interest. Dr. lings does not admit that syphilis wiped out the nd builders who occupied the shores of Lake nigan before the Indians came there, and he makes pronouncement as to whether the Indians infected whites with syphilis or vice versa. He arraigns Indians for their failure to adopt systems of ge and refuse disposal, and for their liability heumatism and malaria. Sagacity is, however, n in their frequent removal from fouled sites h enabled them to avoid typhoid fever; nomadic -air life accounts for their relative escape from rculosis. Names of world-wide interest occur e story—e.g., Marquette, George Washington who of "cynanche," Alexis St. Martin, and Dr. mont, Abraham Lincoln, several members of e family died of "milk sickness." Readers ght up on Osler's Medicine will be prepared for mention of typho-malarial fever, a combination iseases not common in other countries. Dr. lings is embarking on rough seas when he suggests "typhoid fever may have evolved" and that "typhoid bacilli may be evolving back into the Salmonella group to produce food poisoning or even harmless bacilli right now and every day, and here." Certainly it is difficult to answer the questions—what becomes of all the typhoid carriers and why are they spreading so little typhoid? The same questions were asked 20 years ago in the Klinisches Jahrbuch. During Sir William Hamer's tenure of office at the London County Council a large reduction of typhoid fever occurred in the metropolis while the "carrier" question was purposely ignored. The report may be studied with profit for its sidelights on epidemiological theory and practice.

[4] L. Andrews: Philippine Jour. Sci., Sect. B. 7, 1912, p. 67.

WOMEN IN INDUSTRY.

THE place of women in modern industry has often been discussed, and the suggestion has been made that her place is in the home rather than in the factory; but appeals to the past, as have been made by such writers as Thomas, Havelock Ellis, and Sir J. Fraser, establish that the home of old not merely held the cradle but was the tribal workshop, and that industries originated in domestic activities started by women. Only in comparatively recent times did the inventive faculties of men bring machines into existence, and with them modern industrial methods which have carried much of the work of the woman from the home to the factory and placed it in the hands of the man. He, however, is no less a stranger there than is the woman, the factory is new to both; but the woman can justify her presence by pointing out that she has only followed her occupations. Interest in such considerations turns on the proof that throughout the ages woman has been accustomed to perform tasks calling for physical strength and endurance, tasks indeed heavier and more strenuous than those which they perform in our factories and workshops to-day. When the question is asked what effort she can sustain without injury and even with advantage, until recently no reply, based on accurate observations, could be given. There has, however, just been published [1] by the Industrial Fatigue Research Board the result of accurate and painstaking investigation into the physique of women in industry and their physical capacity. This report is consequent upon, and confirmatory of, an earlier inquiry[2] into the question of carrying. The metabolic cost of carrying loads seems to depend, in large part, on the disposition of the load; while any load which brings about any considerable departure from the erect posture, especially if this be associated with induced abnormality of gait, inevitably leads to a high physiological cost. The first part of the report presents data gathered from 4366 females, aged from 14 years upwards, some being college students, but most of them factory operatives. Such material has been collected before for males, in connexion with army recruiting, and deductions drawn from the new observations are found to fall in line with those based on male records. Mental activity is associated with physical development, the students being taller, heavier, and stronger than the operatives; moreover, they are stronger per unit of height and weight. Apparently mental activity enables the muscles to be used more effectively. This conclusion accords with that of Martin in America: "The most striking feature with regard to her strength is its co-relation with mental activity rather than with muscular development." The same underlying principle was found among the industrial group, since the members of an unemployed group were of equal weight but of less height, therefore smaller and stouter than their employed sisters, and they were on the whole less muscular as proved by the tests. These tests consisted in pulling against a recording spring,

[1] The Physique of Women in Industry. By E. P. Cathcart and Others. Industrial Fatigue Research Board. Report No. 44. H.M. Stationery Office. 1927.

[2] The Effects of Posture and Rest in Muscular Work. Report No. 35. Ibid.

gripping and crushing between both hands; in fact, the attributes of the unemployed group certainly suggested that they were less employable and so had either failed to obtain employment or had drifted out from it. The second part is concerned with determining the optimum load for carrying. As a result of careful experiments, described in detail, on the metabolic cost of human porterage by various methods, and its effect upon pulse and blood pressure, the conclusion is reached that loads for women should not exceed 40 per cent. of the body-weight for continuous carrying, and 50 per cent. for incidental or occasional carrying. Translated into average weights, these percentages are about 45 and 55 lb. respectively. Field investigation of practice in many widely different industries, including the chemical, tinplate, engineering, pottery, textile, brick-making, and paper trades, revealed that women tend to conform closely to the weights suggested above; they are generally self-protective in their choice of the size of load, and know to a nicety their own capacity. But young persons, particularly young lads, tend to tackle weights outside what is reasonable; this group of operatives needs supervision. Where heavy work is continuous the maintenance of a steady rhythm is of great assistance to the ease with which energy can be expended. Legislation regarding weight-carrying in different countries is given in an appendix, reference to which establishes the need which exists for such a scientific investigation of the whole subject as that which is now before us. It is an example of research carried out with forethought by a team of investigators whose observations and data have been treated with skilled statistical method. Little doubt, therefore, can be felt that the conclusions arrived at, even though tentatively put forward, approximate closely to certain facts.

THE MANAGEMENT OF LACTATION.

NOTHING is commoner in discussions on breast-feeding than reiteration of the statement that demand creates supply, and medical opinion in this country and America generally favours the view that 3 to 4-hourly feeding (five or six feeds a day with no night feeding) provides the amount of stimulation desirable to maintain the function of lactation. On the continent more frequent stimulation is recommended, Marfan and Variot in France, and Finkelstein in Germany, advocating 3-hourly or even 2½-hourly feeding. In a recent paper[1] Dr. Margaret Emslie describes an investigation which she carried out over a period of six years among breast-fed infants attending the welfare centres at Croydon, with the objects of determining (1) whether there is a lactatory "zone of efficiency" as in other physiological functions, with wider "thresholds" than those suggested by 2-hourly maximal or 4-hourly minimal stimulation; (2) whether the result of mammary activity, as shown by the nutrition of the child, varies with the amount of stimulation; and (3) whether, within the zone of effective action, there is a point of election which will provide the optimum for both mother and child, nervous as well as physical factors being taken into account. The cases dealt with included 103 infants who were fed four times a day and a small group of ten infants whose feeds were reduced to a total of three a day, usually for reasons connected with the mother's health and ability to continue nursing. In the early stages of the experiment (1920–21) the transition from 3 or 4-hourly feeding was carried out so gradually that the system of four feeds a day was only completed by the sixth month; later, when the well-being of both mother and child on the smaller number of nursings had proved itself, the process was speeded up, and the four-feeds-a-day system was often fully established by the sixth week, and sometimes sooner. The mother's understanding and coöperation were secured in every instance, and no single case occurred in which it was necessary t return to the old routine, either because the bab failed to gain the regular average of 6 to 8 oz. a wee which was taken as the standard of success, or becaus the mother was suffering from over-distension of th breasts or failure in the supply of milk. Tests carrie out occasionally showed no undue increase in th amount ingested at one nursing, and no abnormalit or change in percentage composition of the milk The average weight-curve of the 103 babies fed fou times a day began and ended (at 12 months) practi cally at the normal level, with a surplus of 1½ t 2 lb. above the normal curve between six and eigh months. Among the ten babies who were reduced t three feeds a day the age of the mothers varie between 24 and 43 years, and the position in famil of the baby between first and fourteenth; neithe of these factors appeared to have any direct influenc on the capacity to maintain lactation under greatl reduced stimulation. Dr. Emslie states that, whil the condition of the child is regarded as the measur of success in lactation, the comfort of the mother a the chief factor in that success is inadequately recog nised. She further maintains that it is precisely th good and conscientious mother, who realises he responsibilities to her husband and her other childre who is the most apt to resort to artificial feedin owing to the continuous pressure under which he daily duties are performed and the interruption c her work at inconvenient hours for the purpose c suckling her infant. The régime adopted by D Emslie avoided these drawbacks, the baby's mea times being fixed at 8 A.M., 12 noon, 4 P.M., and 8 P.M and this relief of both physical and nervous strai on the mother may have, she believes, a valuabl influence on the continuance of lactation witho impairing the health or progress of the child.

[1] The Function of Breast-feeding, Archives of Disease in Childhood, October, 1927.

THE CAREER OF FRANCIS HOME.

AT a meeting on Dec. 7th of the Historical Sectio of the Royal Society of Medicine, Fleet-Surgeon W. H Home read a paper on Francis Home, 1719–181 first professor of materia medica in the University o Edinburgh. As an Edinburgh student he was a early member of the Medical Society, and on th outbreak of the war of the Austrian Succession i 1742, he served in Flanders as medical officer to th 6th Inniskilling Dragoons. To prevent fever, Franc Home in 1748 ordered that dragoons "shall drin no water without it be first boiled, and a little brand or gin mixt with it." He was at Dettingen an Fontenoy, gained the approval of Sir John Pringl the Physician-General, and studied at Leïden in th intervals between campaigns. In 1750 he took th M.D. of Edinburgh, noting in his thesis that he ha not in Flanders seen a case of fever with a temperatu above 104° F.; this was the first clinical report temperature in fever by a British physician. Thoug Boerhaave, primarily a chemist, was dead, he w still the inspiration of Leïden, so probably muc attention was given to chemistry there. At an rate, Home began at once to write on this scienc first analysing the water of a spring at Dunse (1751 in 1756 he published lectures on "bleaching," advisin dilute sulphuric acid for "souring" cloth, whic greatly helped the linen industry for the next 5 years. The Government paid him £100 for h experiments, and his book was translated into Germa In this same year was published his "Principles Agriculture," said to be the first attempt to brin chemistry to the aid of agriculture. For this boo he was given a gold medal; a French translation w issued in Paris in 1761, with the approval of th French King, though we were at war with Franc and two German editions came out, the translat declaring Home was the first to show that plan got some of their food from the air. In 1758 appear his "Principia Medicinæ," long a standard text-boo and in the same year, as several children died measles in Edinburgh, he tried to lessen the risk

inoculation, as had been recently done for small-pox. He made the attempt in 12 cases, and noted that the inoculated disease had a shorter incubation and a milder course than the natural; thus he seems to have anticipated the recent work on measles prophylaxis. In 1765 he wrote on "croup," suggesting that laryngeal diphtheria was a different disease from the angina maligna that everyone knew. This error was not completely set aside until the time of Bretonneau (c. 1820). In 1765 Home was physician to the King, and in 1768 was appointed to the newly established chair of materia medica and took his turn in charge of the university clinical ward in the Royal Infirmary. In the library of the Royal Society of Medicine are MS. notes of his lectures on materia medica (1775) and clinical medicine (1776–77). In his writings he shows a good grasp of scientific method, but is much hampered for want of modern equipment. In his last book, "Clinical Experiments" (1781), he announces that diabetic urine can be fermented with yeast, and with J. Black, professor of chemistry, reports the amount of sugar in this urine. In 1798 he retired from his chair, being succeeded by his son, James Home. He died in 1813, and is buried at Earlston, in Berwickshire, where he had bought a small estate, Cowdenknowes.

THE DIAGNOSIS OF LOBAR PNEUMONIA IN CHILDREN.

LOBAR pneumonia, says Dr. E. Apert,[1] is sent to hospital with a wrong diagnosis more often than any other disease of childhood. In cases diagnosed as meningitis or acute appendicitis the true condition is often found to be pneumonia, whilst in those originally classed as pneumonia it proves to be pleurisy, acute tuberculosis, typhoid fever, or scarlet fever. For the avoidance of these mistakes it is well, he says, to bear in mind that in childhood the disease is mild, so that even patients whose temperature is high at the beginning of an attack may not seem ill to an unobservant mother. The rigor of onset is absent, but is sometimes replaced by a convulsion, and this is often accompanied by other possible signs of meningitis such as stiffness of the neck and slight spasm of the hamstrings. Otherwise, however, there is no evidence of meningitis; the attitude of the child is different, and the cerebro-spinal fluid is generally normal, though it occasionally shows a very slight increase of cells and albumin, whilst there are usually positive signs which indicate the correct diagnosis of pneumonia. Of these labial herpes is important. Often the papules are very small and transient, disappearing within 24 hours, but Dr. Apert considers that they are valuable evidence of pneumonia and must be carefully looked for. Pain in the abdomen, referred from right-sided pneumonia, may superficially resemble acute appendicitis, especially if it is accompanied by vomiting, as it may be in either condition; but careful palpation will almost invariably distinguish the two. By gentle and progressive palpation it is nearly always possible to press right down into the right iliac fossa in pneumonia without causing the mild pain, and only very rarely does pneumonia cause abdominal pain which truly resembles that of appendicitis. Dyspnœa is absent in children, except when consolidation is extensive, and the child lies on either side without discomfort. Below 12 years of age expectoration of sputum is uncommon, but in young children it can sometimes be produced by putting the finger down on the base of the tongue and causing a spasm of coughing with the ejection of sputum on to the back of the tongue, whence it can be removed with the finger. It is then sometimes rough and reddish, as in adults. The cough is less violent than in adults and less restrained than in pleurisy; its presence is very important, however, in directing attention to the chest. The physical signs are much less marked than in adults and are absent when consolidation is confined to a small patch; dullness is best elicited by very light percussion. Alteration in breath sounds can often only be detected by very careful auscultation, and changes are much more variable than in adults, the sounds being always harsher. It is important to listen in the axilla as sounds tend to be conducted there by the fissures in the lung. Tests of vocal resonance and fremitus are of very little value in children, and sometimes tubular breathing does not make its appearance until after the crisis. These facts, Dr. Apert points out, account for many of the difficulties of diagnosis, but errors can for the most part be avoided if they are recognised and if a methodical history is taken from the parents.

PSYCHOLOGY OF MILITARY PRISONERS.

THE future of court-martial prisoners in disciplinary barracks in the United States, who return to duty on conclusion of sentence, has been made the subject of inquiry in the *Military Surgeon* for November by Lieut.-Colonel E. King, Medical Corps, U.S. Army. This future is found to be often unsatisfactory, the men proving themselves a risk to the service, being essentially undisciplinable. Colonel King believes that every such case should have a special medical examination to decide whether his discharge should not be applied for. In fact, of 165 such men in three years 30 per cent. appeared so unsatisfactory that their discharges were applied for, and 25 per cent. more seemed to merit similar treatment. In the suitable cases discharges would certainly save money, and Colonel King points out that the process would increase efficiency of units and lessen criticism of the service. He concludes that deserters, particularly those who desert early in their service, are military weaklings, and that all deserters should be sent before courts-martial, it being useless to keep in the army deserters of short service. Important psychological questions are opened up by such conclusions, and comparisons would be interesting between the American circumstances and those which prevail in the armies of other nations, consideration being had to the methods of recruitment.

IMPURITIES IN ETHER.

IT has long been known that when light acts on ether in the presence of oxygen peroxides are formed. At first it was believed that hydrogen peroxide was the only product, but later it was shown that during the oxidation a substance was formed which has an intensely pungent odour and exerts an irritating action on the skin and tongue. Although many chemists, including Berthelot, Dunstan, and Wieland, have worked on this subject, none has been able to determine beyond doubt the chemical composition of this organic peroxide. Wieland considers that it is dihydroxy-ethyl peroxide. Hitherto all attempts to obtain it in pure form have failed on account of the readiness with which it explodes. A paper read last week before the Society of Public Analysts by Mr. G. Middleton, B.Sc., and Mr. F. C. Hymas, B.Sc., two associates of the Institute of Chemistry attached to the staff of the British Drug Houses, Ltd., gave a useful review of the methods in general use for detecting peroxide in ether. They find, as others have found, that different samples of ether vary considerably in the readiness with which they undergo change in daylight in the presence of oxygen, and they express the view that entire freedom from both peroxide and aldehyde is essential in securing the stability of ether. In order to carry this into effect the official tests adopted by the different pharmacopœias for detecting peroxide in ether may need some revision; ten of these, including the British Pharmacopœia, adopt the potassium iodide test. The method of the present British Pharmacopœia is sensitive to one part of peroxide in two millions; Middleton and Hymas describe tests by which one part in 50 millions of ether can be detected and estimated. A colourless solution of ferrous thiocyanate is run into a bottle containing

the ether to be tested, the volumes being adjusted so that the vessel is filled. It is then stoppered and shaken, and the colour produced is observed by comparison with a standard solution of cobalt sulphate or by means of tintometer glasses. In this way a quantitative figure can be given in terms of parts per million, and the authors suggest an upper limit for the amount of peroxide to be permissible, which is very much less than that which can be detected by the present official pharmacopœial test. Routine testing over several years has shown that the ferrous thiocyanate test is easy to apply and gives consistent results. By its aid it should be possible readily to eliminate samples of ether which are unsuitable for narcosis.

AN INTERNATIONAL MEDICAL ASSOCIATION AND CENTRE.

IN July, 1926, a body called the Association Professionnelle Internationale des Médecins was formed by a group of 14 delegates of medical associations who chose as their secretary-general Dr. Fernand Décourt, President of the Union des Syndicats Médicaux de France, and selected Paris as their headquarters. On Sept. 29th of this year the delegates met again in Paris, this time in the fine new building at 10, Place d'Iéna, which has recently been opened as a Foyer Médical Franco-International. Twenty-two countries have now joined the Association, each of which has designated as its correspondent either the president or the secretary of the national association. The representatives present were Drs. Schneider (Germany), Stritzko (Austria), Schaeffer (Denmark), Fortuyn (Holland), Fedders (Lithuania), Schaeftgen (Luxemburg), Przyborowski (Poland), Tomesco (Roumania), Rystedt (Sweden), Vuilleumier (Switzerland), and Farkas (Jugoslavia and Czechoslovakia). Dr. Alfred Cox (England) was present in an unofficial capacity, the British Medical Association not having decided whether it will join the International Association. It is stated that several important professional questions have already been taken up by the Association and liaison has been established with the International Labour Office in Geneva. The Foyer Médical has been built as a commercial undertaking, the capital having been subscribed by investors. It contains comfortable reception rooms, restaurant, bar, tea-room, and reading and writing rooms. A tourist bureau provides information on hotels and professional information on clinics, hospitals, and specialists can be obtained. The aim of the promoters is to make it both a club and a centre of information for doctors of every nationality.

THE RETIREMENT OF PROF. MACALLUM.

THE retirement is announced of Dr. A. B. Macallum, Professor of Biochemistry in McGill University, Montreal, from the chair which he has filled with much distinction since his translation seven years ago from Toronto. Prof. Macallum began at Toronto, where he was lecturer in physiology, a full experimental course in physiology and biochemistry in 1886, and his methods were of a thorough sort not familiar at that time. The students were made to do the experiments themselves, which were at first of a simple kind, but the course was complete in three years, almost as complete as it is anywhere to-day—and nothing exactly like it obtained elsewhere, except at Harvard, where Prof. Bowditch had an experimental course from 1892 on. The students were gradually taught to appreciate the modern views of physical chemistry (derived from Van't Hoff's and Arrhenius's conceptions of physical chemistry) and colloidal chemistry as applied to biochemistry. In 1891 Macallum was appointed professor of physiology and biochemistry at Toronto, and the researches to which he gave particular attention were those on the origin of hæmoglobin from the chromatin of the hæmotoblasts, which led to the attempt to determine whether chromatin is an iron-holding compound. This was demonstrated by the results of research of three years, which showed that the chromatin of every cell is an iron-holding compound, and that hæmoglobin is, as it were, a degeneration product of chromatin. This explains the absence of a nucleus from the red blood corpuscles of mammals. There is a nucleus in the red blood corpuscles of the lower vertebrates, but the chromatin in it is in a degenerated form and because of this nucleus the red cells of these lower vertebrates cannot bring about cell division. In 1897 he was made F.R.S., and there followed researches into the absorption in the intestines of iron compounds into the inorganic composition of the blood plasma in vertebrates and invertebrates with closed circulation and into the inorganic composition of the cell, with the discovery of a method for detecting microchemically potassium, chlorine, phosphorus, calcium iron, and copper. In 1920 Macallum, now administrative chairman of the Canadian Research Council, was appointed professor of biochemistry at McGill, and his most recent researches have been into surface tension and its effects on determining the distribution of salts in living matter; the problems here are now being investigated.

All physiologists will join us in wishing Prof. Macallum an extended period to enjoy leisure, and—we may be certain—to continue the studies to which he has devoted his life. He is succeeded in the chair at McGill by Prof. J. B. Collip, well known in association with the discovery of insulin, which he made available for clinical purposes, and later for his parathyroid research.

WE have received a copy of the eighty-fourth annual issue of the Medical Directory, bringing the information obtained in 1927 fully up to date. The volume has increased in size by some 34 pages since last year, largely owing to the inclusion of 731 more names. This increase is conspicuous in three of the classified sections—namely, London (plus 114), Provinces (plus 521), and Wales (plus 46); whilst both Scotland and Ireland show distinct reduction of numbers—83 and 72 respectively. The diminution of 35 in the Services is but a continuance of the tendency observed since 1922, but the remarkable increase in the section of Practitioners Resident Abroad continues unabated, this year amounting to 240. The useful information at the front of the Directory is largely unchanged, trifling inaccuracies in the section of Titles Conferred having been made good, although there is still a curious survival under Appointments to the Royal Family. We greatly welcome the re-insertion of the list of Coroners in England and Wales, to which the editors have added an invitation to readers to supply corrections. The list of certified masseurs has increased by a column or two, and practitioners will welcome the Directory of Nursing Homes, which is a new feature of the 1928 edition, to be found on pages 413–14. The Directory, which remains of convenient size and format, may be had from Messrs. J. and A. Churchill for the usual price of 30*s*.

Prof. Robert Howden retired on Sept. 30th from the chair of anatomy in the University of Durham College of Medicine, and it is felt that many of his old students, colleagues, and friends will welcome an opportunity to express their gratitude for his work as anatomist, teacher, and administrator. He has served the medical school devotedly for 38 years, whilst the profession at large has profited by his admirable editing of "Gray's Anatomy." The proposed testimonial will take the form of a small memento and a cheque and it is asked that contributions should be sent to Sir Joseph Reed, at the College of Medicine, Newcastle-on-Tyne, by Dec. 31st.

Mr. Horace H. Rew has been appointed Secretary of the Conjoint Examining Board in place of Mr. F. G. Hallett, who resigned, as we have already stated, as from Dec. 5th.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLIV.—THE TREATMENT OF PHLEBITIS.

PHLEBITIS occurs in two forms, (1) the plastic, and (2) the suppurative. In the plastic form of phlebitis inflammatory changes occur in the endothelium of the veins and as a result a clot or thrombus appears within the vein. Organisation of this clot by fibrous tissue may occur, the vein being transformed into a fibrous cord. In other cases the clot becomes softened and broken down and the circulation of blood through the vein is resumed. During this process a portion of the clot may become detached and pass to the lungs, resulting in pulmonary embolism. In the suppurative form the vein and the clot which it contains become invaded by pyogenic organisms; leucocytes enter the clot and cause it to break down into a purulent fluid.

Ætiology of Plastic Phlebitis.

Plastic phlebitis may be a result of (1) infective fevers, especially typhoid fever, (2) gout, (3) post-operative thrombo-phlebitis, (4) puerperal phlebitis or phlegmasia alba dolens, or (5) trauma, usually but not always, in cases when the veins are varicose.

Preventive Treatment of Plastic Phlebitis.

In the *infectious fevers*, especially typhoid fever, phlebitis of the lower limbs is not uncommon. The diet recommended in typhoid fever was at one time confined to milk and this substance contains a considerable amount of calcium salts (½ g. per litre: R. Hutchison). It is probable that in a long illness the coagulability of the blood will be increased on an exclusively milk diet and as a prophylactic measure in typhoid fever other liquids, such as beef-tea and lemon-water, should be given to avoid a diet solely composed of milk.

In *gout*, where the phlebitis is often multiple and sometimes symmetrical, the diet should be regulated and appropriate medical treatment, such as colchicine, opphan, and Contrexéville water should be prescribed.

In *post-operative thrombo-phlebitis* we have a condition which needs the urgent consideration of both physicians and surgeons. There is an alarming increase of pulmonary embolism and many deaths result from it after laparotomy. The work of J. G. Clark,[1] who has brought forward many convincing arguments to support his thesis, should be better known. He includes that post-operative thrombo-phlebitis results from trauma to the deep epigastric vein during manipulation of the abdominal wall at operations. He has shown that the clot spreads to the deep epigastric vein on the opposite side and to the iliac vein. The long interval, 8–15 days, which intervenes between the operation and the appearance of the thrombosis in the femoral and iliac veins suggests a slow process with gradual extension of the clot into the femoral vein from a focus some distance away. The absence of much fever and the fact that the pulse is slightly, if at all, raised in rate suggests a traumatic lesion of the vein rather than an infective one. In one case, after a patient had been operated upon and had developed a typical thrombo-phlebitis with œdema of the right leg, it became necessary to perform a second laparotomy. At this second operation, two months later, both the epigastric veins were found to be tense, hard, and as large as goose quills, while the right one was found to be decidedly varicose and to contain phleboliths. The block in the iliac vein may or may not be complete; if it is complete we get a swollen œdematous leg whilst if it is incomplete, pulmonary infarction may occur without swelling of the lower limb. It is clear from this that surgeons should use the utmost gentleness in manipulating the abdominal wall during operations. I am strongly against the modern habit of trying to remove an adherent appendix through the same abdominal wound that has been used for inspection or operative procedures in the upper abdomen. A great deal of stretching and pulling of the parietes occurs and it is far better to make a second incision over the appendix, if its removal is required after an operation on the upper abdomen. It is also clear that after abdominal operations the patients should be encouraged to move the legs as soon as possible so as to prevent stagnation of the circulation. W. A. Lister[2] has shown that the commonest source from which massive emboli arise is in the iliac veins and their larger tributaries, and he suggests as a preventive measure that movements of the abdominal wall should be encouraged after operation as soon as possible. He also suggests that massage to the lower limbs and breathing exercises should be undertaken as soon as possible after an operation on the abdomen. Another factor which may be of some importance in producing stasis in the femoral vein is the acute flexion at the groin which is produced by placing a bolster beneath the knees in order to prevent the patient slipping down in bed. The use of this support should be condemned.

After operation it is advisable to begin, on the third or fourth day, to give a mixture containing potassium citrate and ammonia three times a day as a prophylactic against clotting.

Prophylaxis against *puerperal phlebitis* is similar to that already described against venous clotting after operation. The influence of puerperal sepsis in this connexion is, however, very important.

Trauma is a cause of phlebitis usually, but not always in cases where the veins in the lower limbs are varicose.

Treatment of Varicose Veins.

The treatment of varicose veins may be summarised as follows:—

(*a*) *Support.*—The use of crêpe velpeau and india-rubber bandages and elastic stockings has been condemned on insufficient grounds. They certainly help to protect the veins from trauma and prevent their over-distension, and in many cases this is the only treatment necessary.

(*b*) *Spa Treatment.*—A great many cases of varicose veins have been greatly benefited by treatment at Bagnoles de l'Orne in France. In my experience the greatest benefit from the hot springs of the spa has been in cases where thrombosis has already taken place in the veins and more or less œdema of the lower limb has resulted.

(*c*) *Surgical.*—Removal of localised bunches of varicose veins may be undertaken by surgical excision. In many cases where the valves of the veins have become incompetent and there is great distension of the veins when the patient stands erect, Trendelenburg's operation of ligature of the saphenous vein in the groin has been used successfully.

(*d*) *Injection.*—In 1919 Sicard[3] proposed to inject fluids into the varicose veins with a view of producing a sclerosing thrombosis. Five c.cm. of a solution of 20 per cent. sodium salicylate are injected into the vein, which becomes hard and a firm clot is produced, which eventually leads to shrinking and disappearance of the varix. Apparently embolism does not occur as the result of this method of treatment.

(*e*) *Treatment when Phlebitis and Thrombosis has Occurred.*—Rest in bed is essential. The limb should be slightly elevated to favour return of the venous circulation. The inflamed vein may be gently painted with liniment of iodine and then covered with warm cotton-wool. If the whole leg is swollen it should be entirely encased in warm wool and covered with thin mackintosh. If the pain is severe, the skin over the painful area may be smeared with a cream made with green extract of belladonna with twice its weight

[2] THE LANCET, 1927, i., 111.

[3] Presse Médicale, June 2nd, 1926.

of glycerine. Massage and friction must not be employed for at least three weeks.

To prevent further clotting, citrate of potash and ammonia should be given, as in the following prescription :—

℞ Potass. citrat.		gr. xv.
Sp. ammon. aromat.		℥ xv.
Ammon. carb.		gr. iv.
Glycerini		℥ xx.
Aq. menth. pip.		ad ½ oz.

Sig. A tablespoonful in water every four hours.

After three weeks, if the leg remains swollen, gentle friction to the skin may be employed but deep massage is contraindicated.

Pulmonary Embolism.

The symptoms of pulmonary embolism appear in most cases with dramatic suddenness. Some 10 to 14 days after an operation or after parturition the patient is suddenly seized with violent pain in the chest. The breathing becomes very difficult and the distress of the patient is very great. If the clot is large enough to block the pulmonary artery or one of its larger branches, the patient may die in a few minutes. If, however, the colt is not so large, the patient recovers and within the next 24 hours a pleural rub may be heard and the patient will bring up a quantity of dark-coloured blood. Within two or three days a dull area may be found at the base of one of the lungs and tubular breathing and increased vocal resonance may be elicited over this area. Indications that pulmonary embolism may occur after an operation are slight. After the post-operative pyrexia has settled down to normal on the third or fourth day, the temperature, instead of remaining quite normal, may show slight signs of oscillation, rising to 99° or 100° F. without any obvious cause. There is usually no pain in the lower limbs, but just before the embolus takes place there may be a little œdema of one or both feet. The prevention of pulmonary embolism is that of thrombosis in the iliac veins. Once thrombosis has taken place the patient must be kept absolutely still and any respiratory exercises and movements of the abdomen and legs must be immediately stopped. Should a clot in a varicose vein show signs of ascending the leg the inflamed vein should be removed and the saphenous vein tied in the groin. It is clear, however, that operative measures on a clot in the iliac vein must be of doubtful value, though in some cases they have been undertaken. When the patient is seized by the crisis of pulmonary embolism, the violent spasm and acute pain are best relieved by a small dose of morphia. In many cases œdema of the lung supervenes and the chest becomes full of bubbling râles. When this occurs one-fiftieth of a grain of atropine should be injected. If there is much cyanosis, oxygen inhalations may be tried, and if the pulse becomes feeble strychnine, digitalis, and camphor should be injected. When once a pulmonary embolus has occurred it is obvious that another portion of clot may become detached and a second attack may follow, and I have seen cases where three or four small emboli have passed into the lungs during the course of two or three weeks and yet the patient has recovered. In view of this, it is essential that the patient should be kept absolutely quiet in bed for a period of four to six weeks until it may be hoped that the thrombosis in the iliac vein has become fully organised.

Ætiology of Suppurative Phlebitis.

The pyogenic organisms reach the veins from a focus of suppuration around them. The most common varieties are the result of (*a*) mastoid disease, resulting in septic phlebitis of the lateral sinus and internal jugular vein ; (*b*) facial carbuncle or boil resulting in infection of the angular vein and cavernous sinus ; (*c*) septic conditions in the abdomen, such as appendicitis, gastric ulcer, and tuberculous glands resulting in portal pylephlebitis ; (*d*) septic phlebitis of the iliac veins may follow certain cases of puerperal infection or uterine and bladder diseases.

Treatment of Suppurative Phlebitis.

(*a*) The infective focus must be drained or removed—e.g., the mastoid process must be drained or the appendix removed.

(*b*) Whenever possible a ligature must be placed on the vein between the affected area and the heart—e.g., the jugular vein must be ligatured at the root of the neck in cases of lateral sinus thrombosis.

(*c*) When this has been done, the inflamed vein should be thoroughly laid open, the septic clot removed, and the cavity thoroughly cleansed and drained whenever anatomical conditions allow of this being done.

After these essential surgical procedures have been carried out, the patient's strength must be maintained by careful feeding ; alcohol and other stimulants should be given when needed, while antistreptococcal serum may be given to combat the toxæmia.

THEODORE THOMPSON, M.D. Camb., B.Sc.,
F.R.C.P. Lond., F.R.C.S. Eng.,
Physician to the London Hospital.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

THE following are some of the 1926 statistics of four English and one Scottish county :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality
Lancasbire .. .. (1,788,500)	15·6	12·0	0·81	1·29	2·2	1·7	7·5	80	6
Durham .. .. (996,700)	22·9	11·5	1·11	0·99	2·2	1·1	11·0	84	5
Cheshire .. .. (654,500)	15·7	11·2	0·74	1·37	1·8	1·6	6·2	70	3
Somerset .. .. (399,500)	15·2	11·6	0·67	1·43	1·6	1·9	4·3	52	3
Stirling* .. .. (79,810)	22·8	10·9	0·64	1·07	1·9	1·2	6·6	70	4

* The figures refer to the county landward—i.e., excluding the burghs.

Lancashire.

Dr. J. J. Butterworth reports that the death-rate from cancer has steadily increased from 0·54 per 1000 in 1900 to 1·29 in 1926. During the last ten years the percentage of male deaths has gradually increased from 42·5 to 47·1. Congenital conditions accounted for 41 per cent. of the infant deaths and respiratory diseases for over 24 per cent. Operative treatment for tonsils and adenoids is not undertaken at the school clinics but only in hospitals by expert surgeons. During 1926 725 children received such operative treatment under the county scheme. The treatment of defects of vision is undertaken in the eye departments of hospitals or by part-time specialists in the county clinics. During the year 3343 children were treated under the county scheme. The dental staff consists of nine whole-time surgeons and one part-time, each assisted by a nurse or dental attendant. There are 18 clinics which serve about 33,000 children. Owing to the large number requiring treatment, the dentists concentrate on the younger groups of children

during the eruption of the first permanent teeth. They also treat expectant and nursing mothers and pre-school children.

The administrative county includes 19 boroughs, 33 urban, and 19 rural districts. Except for outlying parishes a constant plentiful and pure water-supply is available. In 99 of the 121 districts the local authorities carry out the scavenging. In 75 districts the contents of privy middens are still removed in the daytime. In 63 urban districts motor vehicles are used for the removal of refuse, but only in two of the rural districts. The county staff are making a survey of all the districts. At August, 1927, 70 districts had been covered. An exhaustive report is prepared on each area and sent to the local authority with request for observations as to the steps proposed to carry out the recommendations. Reinspections of the districts are made from time to time. Special inspections are made as required, in connexion with rivers pollution, milk-supply, outbreaks of infectious disease, &c. The time limits allowed by the various local authorities for the emission of black smoke are given. Seventeen authorities allow 10 minutes in the hour, four allow 12, and the urban district of Turton heads the list with 15. Such limits reduce smoke abatement to a farce. There is said to be a shortage of houses in some of the districts and "serious" or "considerable" overcrowding in four boroughs and four urban districts. The erection of new houses shows a marked increase compared with the previous year. Thus during 1926 8397 houses were erected and 3211 local authorities' houses were in course of erection at the end of the year, the comparable figures for 1925 being 6859 and 1692 respectively. Six joint regional planning committees have been established. The Manchester region includes areas in Cheshire, Derbyshire, and Yorkshire. The other five are for S.W. Lancashire, N.E. Lancashire, and in the neighbourhood of Lancaster, Preston, and Fylde respectively. The clean milk competitions promoted by the county council and the County Milk Recording Society do not as yet attract many competitors. There were 7 for No. 3 competition in 1926 and there are 15 for No. 4 competition in 1927. The public analyst, Mr. G. D. Elsdon, referring to the test introduced by his predecessor for determining the amount of dirt in milk, shows that there are far fewer samples containing dirt since this test was started. Thus in 1917 there were 453 dirty samples to 2457 clean. In 1922 there were 339 dirty to 2475 clean, and during 1926 not one sample of milk was returned as adulterated by dirt. Mr. Elsdon goes on to point out that much of this improvement is due to the fact that the once dirty milk has been cleaned by an efficient sieve or a centrifugal cleanser. He goes so far as to suggest that if these methods of cleaning dirty milk could be prohibited there would be an immediate improvement in the production of really clean milk. There were 111 notifications of small-pox with one death; and 159 notifications of encephalitis lethargica with 88 deaths. The county council is the maternity and child welfare authority for 75 of the 121 districts, and has a scheme in preparation to meet the puerperal fever regulations. There were 172 notifications of ophthalmia neonatorum; details of the results are incomplete but include one case of total blindness and five of impaired vision. In December a handy woman was successfully prosecuted for practising as a midwife.

The county council has established two antenatal centres which are supervised by obstetricians from Manchester and Liverpool respectively; and have made arrangements for the admission of parturient women to 13 maternity hospitals or homes in different parts of the county. The orthopædic scheme has been greatly extended by an increased number of local authorities joining in. The Biddulph Hospital is expected to be ready for patients before the end of 1927. When this is completed there will be three centres covering most of the county, each with its own hospital, country hospital, and out-patient centres with the whole of the work conducted by orthopædic surgeons and nurses.

Durham.

Dr. T. Eustace Hill reports that 5791 cases of small-pox were notified with 11 deaths. In December a conference of medical officers of health and of medical officers of hospitals was held in Durham and recommended a more stringent enforcement of the Vaccination Acts and a pooling arrangement for isolation and small-pox hospitals. At the end of the year there were 592 hospital beds available for small-pox. There are 31 urban and 14 rural districts in the administrative county, and the county council is maternity and child welfare authority for all except the boroughs of Hartlepool, Jarrow, and Stockton and Whickham U.D. Dr. Hill thinks the scheme to comply with the puerperal fever regulations will involve considerable expense and will be no easy matter to work in a county area owing to the need for promptitude. He considers that the local sanitary authorities should be responsible for the bacteriological examinations. The county council has already arranged for the admission of puerperal fever cases to the Princess Mary Maternity Hospital, Newcastle, and are considering the questions of providing the services of consultants and special nursing assistance. There were 52 notifications of encephalitis lethargica and 43 deaths. During the last ten years, while the English death-rate from cancer has increased from 1·21 to 1·36, the county of Durham rate has increased from 0·73 to 0·99. Dr. Hill knows of no circumstances in the county, such as occupation, &c., which would explain the low cancer mortality in the county. He thinks it is probably due to a larger proportion of the population being at the lower age-periods.

Special antenatal sessions were held at 21 centres and at the County Maternity Home, Bishop Auckland, and the Richard Murray Hospital, Blackhill. The expectant mothers who attended during the year numbered 2425 (total births, 22,802). The work of the centres was considerably interfered with by their being used for the distribution of milk during the coal stoppage. There was no evidence of any starvation among those attending the centres; in fact, it was noticed that many babies were in better condition because they were more regularly fed and their mothers had more leisure to take them out and give them fresh air. The voluntary workers worked very hard during this emergency period, and an enormous amount of work was thrown on the health visitors by the distribution of dried milk and arrangements for free meals. During most of the period from May to the end of the year 30,000 expectant and nursing mothers and children under 3 years were in receipt of dried milk and meals free or at a reduced price. The cost for the year ended March 31st, 1927, of this provision was £95,945. Children between 3 and 5 years were provided with breakfasts and dinners at the 309 canteens organised by the Education Committee. Expectant mothers in the last three months of pregnancy had the option of milk or meals, but only 1 per cent. chose the meals because they could not leave their homes twice a day and sacrifice two hours daily for the purpose. Considering that all the cooking arrangements, &c., for the canteens had to provide for the daily feeding of over 100,000 individuals, the efficiency of the scheme was marvellous. Canteen committees were formed, boilers bought or hired, and fires were arranged either under penthouse roofs or in the open. Men, who had been army cooks, gave valuable service. Incidentally, many parents received useful lessons on the provision of good plain economical dinners for their children, and mothers were brought in touch with the work of the centres who had never been there before.

The number of confinement cases admitted to the five hospitals included in the county scheme numbered 790. The hospital beds available for tuberculosis cases, numbering 446, are insufficient, and there is a

waiting-list of about 200. An excellent new, specially built, venereal diseases centre was opened in the Stockton Hospital grounds during the year. Although 3924 new houses were built by the local authorities during the year and 3354 others are in course of erection, the shortage of houses and overcrowding are deplorable. Dr. Hill also laments the extremely unsatisfactory position of the rivers pollution question. To conclude on a bright note, however, the general death-rate and the infant mortality-rate were the lowest on record.

Cheshire.

Dr. Meredith Young reports that all the county schemes for the betterment of the public health have grown in size and complexity. The deaths from encephalitis lethargica in the county in 1926 were 31, in 1925 25, and in 1924 32. Dr. Jean R. Shaw, the maternity and child welfare officer, says the County Nursing Association is extending its activities and each year there are fewer areas without the services of a trained midwife. This association is successful in securing midwives with a high standard of efficiency. There are six county midwives working in districts not touched by the Association. Each of these receives a grant of £60 a year until she has a practice sufficient to support her. Altogether there are 259 practising midwives, 215 trained and 44 untrained. Nine are unable to take the temperature or pulse. One midwife, living outside the county, engaged to attend a woman, who had a history of ill-health, only summoned a doctor when the patient was moribund after labour. Her name was removed from the midwives' roll. Monthly lectures have been held for the midwives at seven centres and were well attended. The county council also give grants to allow two of the midwives, who have been practising in the county for five years, to attend a "refresher" course at Plaistow every year. About 59 per cent. of the mothers were able to breast-feed their babies entirely at the end of six months. This is the lowest percentage of breast-feeding since infant welfare work started. Owing to the shortage of houses, many young couples are unable to start housekeeping in their own homes, and in consequence have needed the help of maternity homes. Up to the present the antenatal centres conducted by local doctors have not proved a success, but an antenatal centre conducted at Stalybridge by a specialist from Manchester was much more popular. At Congleton the local panel committee objected to the establishment of an antenatal centre under the supervision of an obstetric specialist living in the neighbourhood. Dr. Young says the whole question of rivers pollution needs serious consideration and that his staff ought to be strengthened by the inclusion of assistants with engineering and chemical knowledge. The grosser pollutions are connected with trade wastes, and in the case of Cheshire the most serious ones are generated at collieries in Staffordshire, which are situated in one of the Cheshire water-shed areas. In most of the districts housing is going forward at a fairly rapid rate, but as the population is growing it will be a good many years before the shortage is overcome.

Somerset.

Dr. W. G. Savage says there were 37 cases of encephalitis lethargica and 25 deaths. The county council authorise eight cases at a time of non-pulmonary tuberculosis being maintained at the Treloar Hospital, and other cases are sent to the Bath Orthopædic Hospital. The tuberculosis death-rate was the lowest on record and is only two-thirds of what it was at the beginning of the century, the main decline being in pulmonary tuberculosis. Unused buildings at Quantock Sanatorium were again used as a summer camp, with much benefit to 40 girls and 40 boys. The tuberculosis officer, Dr. L. J. Short, shows that the dispensaries are well used for consulting purposes. Of 1683 new cases, 354 had no bacilli in their sputum. Of those with bacilli in their sputum 15 were at stage 1, 88 at stage 2, and 52 at stage 3. Of the remaining cases, 96 were non-pulmonary tuberculosis, 929 were no tuberculous, and 149 were still under observation a the end of the year. During the years 1912–26 7185 patients came under treatment, of whor 32 per cent. are said to be cured, 23 per cent. to b at work, 9 per cent. to be not working, 25 per cen to be dead, and 11 per cent. to have been los sight of. Of the patients admitted to Quantoc Sanatorium during the year 91·6 per cent. were unf for any work and 8·4 per cent. were fit for light worl Of the patients discharged, 54·4 per cent. were fit fo full work, 24·4 per cent. for light work, and 21 pe cent. were unfit for work. The average duration stay since the sanatorium was opened in June, 192 has been 140 days. Antenatal work by the midwive is growing slowly. Antenatal cards are supplied t them and examinations of urine, &c., are done fo them in the county laboratory free of charg Leaflets to expectant mothers are also supplie A special effort began in May, 1926, to detect a cases of rickets at an early stage and bring the under treatment. With this object the visiting infants has been extended to the end of the secon year. At the end of April, 1927, light treatment w in operation at three of the centres. The 673 cas of crippling dealt with by the county orthopæd scheme included 39 cases of tuberculosis, 90 infantile paralysis, 83 of rickets, and 67 of knoc knees (mostly old rickets). Some of the other cas dealt with were spastic paraplegia 27, congenit dislocation of the hip 25, club foot 37, claw foot 2 scoliosis 21, torticollis 10, and postural deformitie 147. There is plenty of water in the county as a whol but there is much failure to distribute it proper among the many small areas responsible for providir their own water-supply. In some urban and ma rural parishes the supply is very deficient. In oth cases there is much waste of money by the duplicati of reservoirs, pipes, &c. The number of new hous erected was 2190, compared with 1386 in 1925 a 973 in 1924. It is still impossible, however, to clo many houses which are unfit for habitation a cannot reasonably be made fit. These numb about 2000. Dr. Savage reports that meat inspecti is becoming more efficient, and he expects mu improvement in clean milk production from t Milk and Dairies Order of 1926. He has much say, however, with regard to the inefficiency of t Tuberculosis Order, 1925, from the point of view the public health. As it is being worked it is doi little more than to eliminate advanced cases tuberculosis when they are ready for the knacke and when they have done their work in infecti the rest of the herd. Early cases of udder tuberc losis are not being notified and are only being detect by the following up of tuberculous milk sampl A whole-time veterinary surgeon should be appoint by the county council to carry out special inspecti and to coördinate the work of the part-time veterina inspectors. Such officer should be on the coun health staff to "enable that preventive outlook to given to the working of the Tuberculosis Orc which is now so conspicuously lacking."

Stirling.

Dr. T. Adam gives full particulars of housi conditions of the three districts—central (populati 27,500), eastern (population 40,692), and weste (population 11,618)—into which the county landwa (i.e., excluding the burghs) is divided. Each distr is administered by a district committee. A surv was made in 1919 and an estimate of houses need made, based on the closing of houses unfit for habi tion and the raising of the general housing standa With the latter object it was proposed to reduce t number of one-apartment and two-apartment hous The first estimate was for over 4500 houses for t three districts. After consideration this estim was reduced to 1140 and schemes were prepared a begun. Before the work was half completed t central government stopped it. In 1919 the build of houses by private enterprise had dwindled

nothing. Since that date there has been a recovery, and the net result for the period 1919 to 1926 is 497 local authority houses and 548 private enterprise houses.

Dr. Adam points out that the inherent difficulties of building houses in bulk are always accentuated when the responsibility is shared by central and local authorities. The aim of the district committees is to close unfit houses with as little hardship as possible, and with this in view the medical officer of health reports such houses when they are vacant. There is, however, such a run on the low-class houses with the cheap rents that they become reoccupied before the local authority has time to close them, and in some cases these cheap houses attract to the district undesirable tenants from outside. Dr. Adam suggests that local authorities be empowered to make provisional closing orders which would become operative on the termination of a tenancy or at the discretion of the local authorities. He also suggests that the grants for the reconstruction of unfit houses made available by the Housing (Rural Workers) Act should be extended to urban housing. Owing to the coal stoppage there was a great increase in the expenditure on milk for necessitous mothers and children. The infant mortality-rate for Stirlingshire was the lowest on record. In the quinquennium 1891–95 the death-rate from all forms of tuberculosis was 2·07. In 1921–25 it was 0·86, and in 1926 it was the lowest on record, 0·64. It is hoped to establish light treatment at the Bannockburn and Camelon Hospitals to save sending patients into Edinburgh and Glasgow. On his comment on the proposed new county dairy by-laws, Dr. Adam thinks the model by-law requiring clean overalls for milkers, &c., should be retained and that it is a mistake in view of tuberculosis risks to lower the cubic space standard from 600 to 500 cubic feet in the case of new byres, and from 450 to 400 cubic feet in the case of existing byres. He further thinks that the Board of Health should give a definite lead with regard to cubic capacity, ventilation, and lighting of byres, seeing that this is not a local question.

The river Bonny has been so polluted of late years that fish could not live in it. Owing to the fact that the local distillery had ceased work and that the Cadder Colliery had been idle for seven weeks, the water improved so much that trout-fishing was resumed. In the three districts among 8092 cows 1 tuberculous udders and 10 cows emaciated by tuberculosis were found by veterinary inspection during the year. The meteorological records show that the rainfall at Falkirk was 38¼ inches, which was 5½ inches more than in the previous year and 2 inches above the average. The falls recorded at two of the reservoirs were 66·6 and 61·7 inches respectively.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 3RD, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 0 (last week 233); scarlet fever, 2148; diphtheria, 1,[illegible]; enteric fever, 89; pneumonia, 1301; puerperal fever, 38; puerperal pyrexia, 86; cerebro-spinal fever, 5; acute poliomyelitis, 12; acute polioencephalitis, 2; encephalitis lethargica, 34; dysentery, 19; ophthalmia neonatorum, 106. There was no case of cholera, plague, or typhus fever notified during the week.

Small-pox was notified from 13 counties, and the number of notifications, 366, is higher than for any week since June 2nd. Allocated to counties, the numbers were as follow: Derby 25, Durham 74, Gloucester 6, Lancaster 36, London 18, Northumberland 22, Nottingham 15, Warwick 3, and the North Riding 4, West Riding 50, Brecknock 8, Glamorgan 36, Monmouth 69. Of the 89 cases of enteric fever only 8 were notified from the county of Hertford.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox (it is now three months since any death was attributed to this disease), 5 (1) from enteric fever, 48 (13) from measles, 7 (3) from scarlet fever, 12 (2) from whooping-cough, 43 (6) from diphtheria, 45 (13) from diarrhœa and enteritis under two years, and 63 (13) from influenza. The figures in parentheses are those for London itself. The deaths from enteric fever outside London occurred one each in Norwich, Bolton, Leeds, and Cardiff. The number of stillbirths registered during the week was 260 in the great towns, including 43 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. (D) H. J. Luck to be Surg. Lt.-Comdr. (D).
Surg. Lt.-Comdr. J. D. Murphy to be Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. A. C. Adderley is placed on the half-pay list on account of ill-health.
Maj. H. C. Sidgwick to be Lt.-Col.
Capt. G. D. Gripper to be Maj. (Prov.).

ARMY RESERVE OF OFFICERS.

Col. H. O. B. Browne-Mason, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt. P. M. Speed, from the Active List, to be Lt.

ROYAL AIR FORCE.

Flight Lt. C. P. Barber is promoted to the rank of Squadron Leader.

INDIAN MEDICAL SERVICE.

Temp. Lt. F. P. Lisboa-Pinto relinquishes his temp. commn.

COLONIAL MEDICAL SERVICES.

Transfers and Promotions: Maj. G. J. Keane, D.S.O., Deputy Director of Medical Services, to be Director of Medical and Sanitary Services, Uganda; Dr. P. P. Martyn, Assistant Medical Officer, British Honduras, to be Medical Officer, Nyasaland; Dr. L. U. Leembruggen and Dr. S. Subramaniam, Medical Officers, Grade I., Ceylon, to be Provincial Surgeons, Ceylon.—*Appointments:* Dr. H. M. Russell, Assistant Pathologist, Medical Department, Gold Coast; Dr. G. Shearer, Medical Officer, West African Medical Staff; Dr. L. R. Wynter, Medical Officer, Leeward Islands; Dr. R. J. Snodgrass, Medical Officer, Fiji; Dr. W. L. Blakemore, Medical Officer, Straits Settlements; Dr. A. L. Kiow, Resident Surgeon, Colonial Hospital, St. Vincent, Windward Islands; Dr. W. B. R. Jones, Assistant Colonial Surgeon, Falkland Islands; Capt. L. A. Celestin, Second Resident Surgeon, Civil Hospital, Port Louis, Mauritius; Dr. A. F. H. Stewart, Medical Officer, District 2 (North) St. Vincent, Windward Islands; Dr. J. W. Murdoch, Second Assistant Medical Superintendent, Central Mental Hospital, Federated Malay States; Dr. M. C. Cairney, Lady Medical Officer, Federated Malay States; and Dr. F. Widlake, Medical Officer, Gilbert and Ellice Islands Colony, Western Pacific.

DEATHS IN THE SERVICES.

Lieut.-Colonel R. B. B. Foster, I.M.S., who died in Dublin of pneumonia on Dec. 5th while home on leave, was the second son of the late Rev. Robert Foster, formerly Chaplain, Royal Hibernian Military School. He was educated at Trinity College, Dublin, where he obtained a Junior and School Exhibition, graduating M.B. in 1900. He entered the Indian Medical Service in the following year, was promoted Captain in 1904, Major in 1912, and Lieut.-Colonel in 1920. He served in the campaign in Somaliland, 1903–04 (medal and clasp); the late war, 1914–18, in Egypt and Mesopotamia (1914–15 Star, General Service and Victory Medals); and on the North-West Frontier of India, Afghanistan, 1919 (medal and clasp). He was only recently placed on the selected list of Lieut.-Colonels and was to have taken up the appointment of Civil Surgeon at Ootacamund on his return from leave. Amongst other appointments he had held was that of professor of hygiene and bacteriology in the Medical College, Madras. He married in 1921 Millicent Wyndham, only daughter of the late Henry Wyndham Ball, of Dublin, who survives him.

CHILD DELINQUENCY.

BY E. A. HAMILTON-PEARSON, M.B., CH. B. ABERD.,

PHYSICIAN, TAVISTOCK CLINIC FOR FUNCTIONAL NERVE DISEASE, CHILDREN'S DEPARTMENT; CLINICAL PSYCHOLOGIST, WEST END HOSPITAL FOR NERVE DISEASE.

THE investigation of the causes of juvenile delinquency on which this article is based has been in progress for seven years. It was undertaken in no narrow psychological spirit, but with the object of exploring all factors, physical as well as psychological and environmental, which might conduce to delinquency; also to ascertain the efficacy of treatment, undertaken on the basis of the understanding of the underlying causal factors and directed to their elimination. The results achieved have been exceedingly good, especially in cases considered incorrigible because they did not yield to ordinary disciplinary methods. It is gratifying, and a testimony to the value of the results, that official centres, unofficially at present, are making increasing use of the work.

The material for the present article was derived from the written statement submitted in support of my evidence given before a Home Office committee set up to investigate the treatment of the young offender. For the purposes of that evidence a rough analysis of an unselected hundred of my own cases was undertaken. Sixty of the cases were delinquencies ranging in seriousness from suspected homicide to cases of uncurbed temper, the remaining 40 were ordinary neuroses.

Neurosis in childhood is treated understandingly because of its possible serious after-effects. Delinquency, although it is more prevalent and frequently has more serious results, is treated arbitrarily and with no attempt at understanding. Yet both states are equally non-adaptations to environmental requirements, but with different manifestations, and they frequently result from identical environments. An environment characterised by harsh unbending discipline may produce a psychological rabbit or a rebel against any form of authority, the difference in reaction being due to the difference in the type of the affected child. In one type the conflict resulting from non-adaptation remains unsolved, a collecting point for irresolutions, a neurosis. In another type the conflict is resolved in action which is at variance with accepted standards, a delinquency.

The delinquents fall into three main categories, the first two of which are differentiated on a basis of mental age, the third because of the existence of a definite physical causative factor: (1) mentally retarded delinquents; (2) delinquents with average or superior intelligence; (3) delinquents because of physical abnormality or disease.

The mental age must be estimated in every case as a routine of examination. Apart from the information gained from the tests, a knowledge of mental age is essential for the correct appreciation of conduct in retarded children. A child of 14 with a mental age of 11 is, for all practical purposes, in its thought processes and reactions to life, 11 years old. The actions of such a child can be correctly judged only from the standpoint of what could be considered normal for an average child of 11.

Mentally Retarded Delinquents.

Group 1.—Thirty-seven of the 60 cases belong to this group, a fairly normal proportion in my experience of the total of cases seen. Certain motives tend to show themselves so frequently as to become almost specific for the group. The most frequent are:—

(*a*) Realisation of inferiority, to which delinquency is a compensatory impulse.

CASE 1.—A boy, aged 16, physically healthy, mental age 12. Complaint: incorrigible stealing, beginning shortly after he commenced work. Investigation showed that he was ambitious to be on terms of equality and friendship with children of his own year-age and realised his inferiority to them, that an unusual popularity with his compeers corresponded with his thefts and that practically every penny was spent on other children. He learned that equality could be gained so long as he had money. The association of money with the satisfaction of his most intense desire led, in the absence of any counteracting inhibition, to his stealing without concealment.

This class of delinquency is the satisfaction of a psychological need, and the only means of preventing it from becoming habitual is to satisfy the need in a more legitimate way. Treatment must be based on the aptitude the majority of these children show for some form of manual training. The power to produce an objective thing, created by themselves, gives confidence and a feeling of capacity which, as a rule, overcome the previous method of satisfying the dominant desire.

(*b*) The continuance of a childish reaction to the environment beyond the age at which it could be condoned and not appear abnormal.

CASE 2.—A boy, aged 7¾, physically healthy, mental age 6. Complaint: incorrigible theft and ungovernable temper. School reported him as backward, docile, and honest. Investigation revealed his strong attachment to the father and intense jealousy of the mother. Any open act of affection between the parents drove the child into a frenzy of rage which culminated in an assault on the mother or theft from her. The boy never stole at any other time or from any other person. Such a reaction to jealousy is only understandable in the light of the child's mental age; it would not be abnormal at 6, but a child of 8, with its greater experience, should have a wider conception of its place in the scheme of family relationships.

It is necessary to study such children carefully and to adjust their environmental conditions in whatever way proves desirable for the production of a normal reaction.

(*c*) Openly stealing an object, because of desire for the object, without reference either to owner or consequences. Part of the educative experience of childhood is the formation of acquired inhibitions, abstract ideas of right and wrong conduct, based on experience and of sufficient power to inhibit an action contrary to the acquired and accepted standard. These inhibitions are usually approximately commensurate with mental age, and depend largely on the form of discipline the child has been exposed to.

CASE 3.—A boy, aged 8, physically overgrown, mental age of 6. Complaint: destructiveness and aimless impulsive stealing. Investigation showed a family history of insanity, a pronouncedly hysterical mother, and no evidence of any exercise of parental control. Open stealing of whatever his fancy dictated, from a bundle of firewood to a bicycle, showed a lack of acquired inhibitions, infantile for a mental age of 6, an exaggeration owing something to basic emotional instability, but mainly due to lack of home discipline.

In such cases the first essential is removal to an atmosphere of stable understanding discipline away from the home environment. After puberty sex constitutes a definite danger to patients in this category with their underdeveloped powers of control. The girls tend to a careless promiscuity, the males provide the greatest number of assailants in cases of criminal assault.

Delinquents with Average or Superior Intelligence.

Group 2.—Twenty-three of the 60 cases belong to this group. In the majority a history of neurosis in one or both parents was elicited. Even mild degrees of parental neurosis may act as a causative factor in child neurosis and delinquency by causing unfavourable environmental conditions; they always call for serious consideration.

Ten of the 23 cases fall between the ages of 13 and 15. Puberty does not, as a rule, initiate abnormal states. The almost normal unbalance of this period of change acts chiefly by emphasising already existing abnormal traits, throwing them into fuller relief. It was possible, in most of these cases, to demonstrate the existence of milder degrees of abnormality some years before puberty.

In this group every case must be investigated separately and on its own merits. Underlying mechanisms have practically nothing in common; they are as various as the children and their environments. Quotation of the salient points of a few cases will amply demonstrate both the variability of mechanism and the fact that a permanent satisfactory behaviouristic result could be obtained only on the basis of an understanding of the mechanism activating the delinquency.

(*a*) Premeditated delinquency—i.e., delinquency, e.g., theft, undertaken with a full knowledge of the wrongfulness of the action and of the punishment involved by detection. A penalty incurred in this way must be exacted; at the same time the psychological factors involved in the execution of the delinquency should be taken into consideration. Many cases show the existence in the delinquent of a capacity for directed observation, an ability to plan on a basis of observed fact, and the initiative and confidence necessary to carry out a plan in the face of known risks—useful qualities to possess if life offers a field for their legitimate use, dangerous if that legitimate outlet does not exist. Sense of power and the excitement gained in outwitting an opponent are the primary activating desires; as a rule the value of the object to be stolen becomes primary at a much later stage.

CASE 4.—A girl, aged 17, physically healthy, intelligence above average. Complaint: a series of cunning thefts of trivial articles. Investigation revealed no previous delinquency. Circumstances drove her to a form of domestic service, the routine monotony of which gave no occupation for an active mind. At first the planning of thefts requiring ingenuity and daring gave exercise for her natural abilities; later, reality could be imparted to the planning only at the expense of the risk of executing the plan. She fully realised the dangers of her position, and that, in the inevitable next step, the value of the object must be a necessary ingredient in any plan to make it worth while as a stimulus. She eagerly welcomed the opportunity of farm training preparatory for emigration, proved an eager pupil, and has had no further trouble.

(*b*) Persistent delinquency, the result of a wrong attitude to certain environmental circumstances.

CASE 5.—A boy, aged 19½, physically healthy, intelligence average. Complaint: recurrent incorrigible delinquency, persisting through nine years, three of which had been spent in a reformatory. Investigation, corroborated by the parents, showed that he was an unwanted child and early resented the lack of affection and indifferent treatment he met with at their hands. The boy could not decide to cut free from people who had practically disowned him, but brooded over the unfairness of his position, deprived of an affection to which he felt he had a right. The boy's general attitude to the parents was, briefly, "if they won't own me then they shall regret having me." Unusual difficulty in his life created an emotional state, the culmination of which was some completely stupid delinquent action dictated by his attitude towards his parents—a boomerang form of revenge.

In such cases punishment will only tend to crystallise the wrong attitude; understanding of the reason for non-adaptation opens a way to complete readjustment.

(*c*) Outbursts of ungovernable temper with attempted assaults upon the parents, the result of inability to accept and adapt to the limitations of girlhood when these become apparent.

CASE 6.—A girl, aged 8, physically healthy, mentally above average. The parents feared that a recently developed ungovernable temper was early insanity. The father was fond of a boy's preparatory school. Investigation showed that she had lived, dressed, and thought as a boy, had never regarded herself as other than a boy, and never had a girl friend. Her age made a more conventional life advisable, and this constituted a sudden call for complete change in the mode of thought about herself and her outlook on life which the child was unable to make. She despised girls with small boy's lordliness. The unfairness of making her a girl when she wanted to be a boy, and her inability to accept or understand the situation, kept the child in a seething state of resentment. Every time the conflict was intensified by experience of the limitations imposed by the conditions, relief came in a fit of passionate anger against the parents who for the first time had failed to make her life smooth for her.

Knowledge of the cause made it possible to help the child to solve her conflict completely and to adjust her education in such a way as to enable her to achieve a healthy attitude towards her own sex.

(*d*) Impulsive stealing of one particular form of article.

CASE 7.—A boy, aged 14, physically healthy but overgrown, intelligence average. Complaint: recurrent theft, persisting in spite of extremely severe corrective measures. Investigation showed that the stealing was of one type of article of female attire, that the garment was a necessary property for the act of masturbation, and that theft only occurred in the presence of strong masturbatory desire. It was a compulsive act as much beyond conscious control as the average spasmodic tic.

First to understand the relationship between the two acts and secondly to help the boy to masturbational mastery was the only way to ensure the cessation of the associated compulsive act of theft.

Delinquency because of Physical Abnormality or Disease.

Group 3.—Mentally these cases belong to the two previous groups; they are considered separately because in each a physical factor is present which conduces to delinquency. Active treatment of the abnormal physical condition is an essential preliminary to the correction of any psychological non-adaptation.

(*e*) Deficient secretion of an endocrine gland producing a condition conducive to delinquency.

CASE 8.—A boy, aged 9, of average mental age, reported to be physically healthy. Complaint: incorrigible theft, mainly of sweetstuffs or of money to buy them. Physical examination revealeda tendency to girdle obesity and retarded genital development. The first recorded theft was of half a tin of golden syrup and the large remains of an iced cake, consumed before breakfast without any ill-effect. Evidence of abnormal sugar hunger and an abnormal sugar tolerance which, with the other physical signs, pointed to posterior pituitary deficiency. A blood-sugar curve corroborated the case evidence of excessive tolerance. The physical condition improved rapidly under treatment with pituitary extract, and with the physical improvement the stealing ceased.

(*f*) Pituitary involvement, a sequela of encephalitis lethargica.

CASE 9.—A boy, aged 14, of average intelligence; encephalitis five years previously had left him somewhat emotionally unstable. Charged with having on several occasions committed unprovoked assaults. Examination showed him to be a case of dystrophia adiposogenitalis. Very sensitive about his appearance, a phobia was gradually forming in his mind that he was an object of derision to everyone who saw him. Anyone smiling as they passed him in the street was quite liable to be assaulted. Only amelioration of the physical state could make it possible to tackle the phobia. Treatment was begun, but after a short period he refused to attend and his case had to be abandoned.

(*g*) Recurrent bouts of violent temper and intractibility, a result of unsuspected physical abnormality.

CASE 10.—A boy, aged 18, intelligence average. Suspected of being mentally deficient because of periodic outbursts of ungovernable temper. Between bouts he behaved normally and worked well. Investigation showed that the bouts of temper coincided with periods of intense headache, bursting in character and localised to the centre of the cranial cavity. X ray photographs showed the sella turcica to be completely enclosed by a thin bone plate. In these conditions periodic fluctuation in gland size would account for the headache. Control of the outbursts of temper could be gained only through alleviation of the physical symptoms.

I hope enough has been said to make clear the advisability of, and the necessity for, an adequate examination of delinquent children by trained medical psychologists. In an article of this length it is impossible to do more than indicate a few of the facts which show the existence of such a necessity. The work constitutes one of the branches of preventive medicine, for which facilities can be gained only as a result of the pressure of an informed medical opinion.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Youthful Marriage Problem.

MUCH publicity has been given here to the marriage of the school-girl daughter of a successful publisher and a college student two years her senior. It is called "companionate marriage." This, we are assured, is not "trial marriage," for the expectation of success is not less than in any other marriage. It is not at all easy to find out in what ways this new marriage differs from the old. The most important would seem to be the youth and dependence of the bride and groom. The bride is to return to school after her honeymoon. Judge Ben Lindsey, who invented companionate marriage—the papers call it "pal marriage"—has had a large experience as judge of the juvenile court of Denver, which has convinced him that very many boys and girls at high school and college are at present enjoying the privileges of marriage without avowing their relations. This has two evil results: first, the encouragement of hypocrisy; and, second, the absence of responsibility in case of pregnancy. Early marriage with the consent of the parents is intended to avert these evils. For economic or other reasons it is assumed that no children will be desired for some years. This arouses interest in both medical and legal circles. Is birth control of any kind desirable in the early years of marriage? Does it tend to subsequent sterility? If desirable, what method of contraception should be recommended? In the meantime a 50-year old statute of the State of California is being tested for the first time; a carpenter is awaiting a jury trial for selling a pamphlet containing information on birth control. The American Civil Liberties Union is backing the defence, which must challenge the statute, since the sale of the pamphlet is admitted. The accused says, indeed, that it is only one of 25,000 that he has sold.

Nostrums and Quackery in the Air.

The absence of monopoly in American broadcasting stations has some advantages—e.g., in the variety of programmes to which one has access—and many disadvantages, not the least of which is the type of advertising to which one may be subjected. Each Wednesday evening, for example, one may hear from station KLZ a certain "Dr." Fisher recounting his latest successes in treating diseases of the eye, ear, nose and throat . . . "consultations free, examinations charged for." The Palmer School of Chiropractic owns a very large station, though it must be admitted that their programmes are free from any kind of advertising. Station KFKB is owned and operated by a quack, who specialises in "rejuvenation," and, alas, there are other stations which lend themselves to imposture of one kind or another.

Athletics and Tuberculosis.

The National Tuberculosis Association has announced its intention of investigating the relation of tuberculosis and competitive athletics. Sanatorium physicians have for long drawn attention to the large number of athletes among their patients, and now educational authorities are beginning to question whether competitive athletics are unduly conducive to active tuberculosis. Dr. Walter L. Rathbun has sent a report to the Association, after examining 1000 high school students in Chautauqua County, New York, in the course of which he says:—

"A relatively large percentage of the active cases of tuberculosis were athletes engaged in the major sports. In one of the Dunkirk high schools three lettermen, the catcher of the Fredonia baseball team, and a member of the Jamestown junior high basket-ball team were found to have tuberculosis. The morbidity is relatively high, and I feel that any boy of high school age who indulges in heavy exercise should be not only examined physically but X rayed."

Prof. Bailey, of the University of California, would go further—he would abolish inter-school competition altogether. The only loss, he says would be a financial one. At any rate, there is good case for investigation.

Accident Prevention.

There were approximately 90,000 fatal accident in the United States last year. Some 48,000, or mor than half of these, occurred upon the streets or i public places, 23,000 in homes, and 19,000 in industry In view of the heavy toll of life, its steady increas from year to year, and the certainty that much the loss is avoidable, the Metropolitan Life Insuran Company conducted last year a demonstration i the City of Albany, N.Y., to show what can b accomplished by organisation and education in single community. The first six months of organise effort gave a reduction of 31 per cent. in accident deaths of all types, 71 per cent. in fatal accidents i the home, and 10 per cent. in non-fatal traff accidents, as compared with the corresponding montl in 1925. The main conclusions from this interestir experience are summarised in a pamphlet issued b the company in conjunction with the New Yor State Conference of Mayors, and entitled "Promotir Community Safety."

Women in Medicine.

The Woman's Medical College of Pennsylvani the only medical college in the United States excl sively for women, is appealing for funds to build new and modern home. It is said to be the olde of its kind in the world, having been founded 76 yea ago by two Quaker physicians. Its success has caus medical colleges, which formerly admitted only me to open their doors to both sexes, and some 70 women are now practising medicine in the State The custom by which large firms establish medic departments and insist on regular examinations employees has redounded to the advantage of medic women. The law in this country insists that when medical man examines a woman professionally, the must be a woman nurse present, which means th the employer must pay for the services of two perso His expenses are correspondingly lessened if t doctor is a woman.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Tropical Medicine Congress in Calcutta.

THE Congress of the Far Eastern Association Tropical Medicine is now very near at hand, and t organising secretary, Colonel J. Cunningham, I arrived in Calcutta in order to coördinate the arran ments. Delegates numbering over 80 are arriving fr 21 different countries. Each province in India is fu represented officially, and it is encouraging to s that over 1100 medical associates have intimated th intention to be present from all parts of the count Names of renown in the medical world will be amo our visitors: Hata from Japan and Shiga fr Korea, Wu Lien Teh from China, d'Herelle fr Egypt, Heiser and Vedder from America; Siam ser H.S.H. Prince Vallabhakara to head her delegate the League of Nations is represented by Madsen a Gautier; the special guests of the Government India are Sir Malcolm Watson, Prof. J. W. Stephens, and Sir Walter Fletcher. Liberal subscr tions to the funds of the Congress have been sent the Maharajahs of Benares, Nepal, Burdwan a Jhalawar. The railways have played up splendid not only have concession fares and privileges b granted with a lavish hand, but three tours of inter have been arranged to afford opportunity of see the charm and mysticism of India.

Social Hygiene.

Last year's visit of the British Social Hygi Council is slowly bearing fruit, in official circles least. National consciousness to the seriousness the scourge in India is slowly awakening. Inter up to the present has been centred around the s

orts, and an increasing amount of care is bestowed n seamen's welfare by the port authorities in ombay, Calcutta, Madras, and Karachi. Happily the ustees of Indian ports have always taken a broad ew of their responsibilities to those engaged in the aritime trade on which the prosperity of their ports pends, but until a Ministry of Public Health is rmed in the Central Government, or even in ovincial Governments, there will needs be little ordination.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Liver Diet in Anæmia.

Prof. Jakob Pal, who made a tour of American edical centres some time ago, was struck by the ourable results obtained with the Minot-Murphy t in pernicious anæmia, and has been using the thod in his own clinic. He uses an extract of er substance, for he finds that the patients refuse take liver itself over a prolonged period, especially hey are in very poor health, and also because it difficult to get fresh liver daily in sufficient quanti-. He prefers a liquid of the consistency of syrup, easpoonful of which is equivalent to about 250 g. oz.) of liver. The really active factor, Prof. Pal nts out, is as yet unknown; some authors attri- e the favourable effect to a vitamin, others to ie stimulant effect on the metabolism of iron. liquid extract which he uses contains 0·92 per t. of iron, and his observations may be sum- ised as follows: (1) In several cases he produced erythræmia, with an increase in blood pressure as olycythæmia rubra hypertonica. This suggests liver has a stimulant effect. (2) Various changes he nervous system, of the nature of the poly- citis so often noted in pernicious anæmia, have pletely or partly disappeared. (3) Secondary mia, especially after serious hæmorrhage, as well he typical chlorosis of adolescent girls (now rather re condition with us) responded to treatment in ost satisfactory way. The characteristic pink plexion which develops even before the number rythrocytes reaches the normal level is due to richer blood shining through the thin transparent utaneous tissues, and only fades when the layer kin and subcutis becomes thicker.

Unsettled Conditions in the Medical Profession in Austria.

he increasing difficulties of life in this country affecting the relations between doctors and their ents and between medical men themselves. The ession has been complaining of late of the iniqui- of the so-called *Krankenkassa* (sick-clubs), which ide compulsory insurance for all wage-earners. e 1888, when the law was introduced, the number ersons insured against illness has been steadily asing, relatively as well as absolutely, and now y 75 per cent. of the population of large towns, cially Vienna, are in one way or another members he of the numerous *Krankenkassa*, and entitled e medical care. This is a result of the bourgeois ming poorer; and the remaining 25 per cent. lso so badly off that they take care to call in the or only when it is absolutely necessary. The ssion, therefore, has for some time been demand- hat people earning more than a certain amount d be exempted from the benefits of the *Kranken-*. Modification of the existing system would re the passing of a special Act of Parliament, the representatives of the profession have re- dly urged the Government to bring in a Bill he purpose. Four hundred Austrian shillings for the single, or six hundred shillings (£18) for arried is the monthly sum which the profession ds as a suitable limit of income, above which e should pay their own doctor's bill, except for operations or prolonged stay in hospital or ng home. This would mean that all the better clerks, persons employed in the civil or municipal services, bank clerks, cashiers, and even managers and directors of commercial enterprises, who have hitherto been entitled to free medical aid owing to their compulsory membership of the *Krankenkassa*, and who have mostly made use of the facilities afforded them, would again become private patients. The profession further demands that no new *Krankenkassa* shall be set up, and that all insured persons shall be entitled to choose their medical man from among a number of practitioners forming a panel for the sick-club. In other words, the present system of appointing doctors at a fixed salary for a certain district, to give medical assistance only to persons belonging to that area, should be done away with in favour of the "free choice of doctor" system. Payment would be made according to work done—i.e., each medical service would be paid for separately. These two postulates have given rise to serious differences of opinion amongst the members of the Medical Organisation of Vienna, which comprises all the 4000 doctors in the city. The group of sick-club doctors with fixed salaries, numbering about 1200, strongly oppose the idea of "free choice of doctor," not because their salaries and pensions would be in danger, but because their organisation has promised that "acquired rights shall not be touched." The conflict has assumed such proportions that the President, Dr. Stritzko, has resigned the position which he has held for ten years, and the 1200 members threaten to withdraw from the organisation. This would naturally weaken to a great extent the position of this body in their struggle with the Government, which is bound to come, as the profession is intent upon enforcing the income-limit for membership of the sick-clubs, especially for those establishments which exist for the officials and servants of the State and municipalities, which have already adopted free choice of doctor.

Blood Transfusion and Splenectomy.

At a meeting of the Vienna Medical College last month Prof. Jagic and Prof. Burghard Breitner discussed the problems connected with various forms of anæmia. Transfusion, they pointed out, is indicated in acute anæmia or oligæmia after severe loss of blood when it often has a favourable effect on the concomitant shock and also as a preliminary to serious operations—e.g., in cachectic persons. Good results are obtained in thrombopenia, agranulocytosis, and true hæmophilia. In leukæmia, especially of the acute variety, much good does not come from transfusion. In many pathological conditions of the blood the spleen has to be attacked as one of the chief hæmopoietic factors. It has been fully established that its removal does not have serious consequences. In the last statistical review of Tschurenkoff and Herfarth it is stated that extirpation of the spleen cures 83 per cent. of cases of hæmolytic jaundice, 80 per cent. of thrombopenia, 78 per cent. of Banti's disease, 25 per cent. of leukæmia, and 20 per cent. of pernicious anæmia. The method is the only one which promises good results in hæmolytic jaundice. It is indicated only in severe cases, in 176 of which it gave a mortality of 6 per cent. The result is believed to be permanent, and the effect is surprisingly rapid, a preventive transfusion being desirable. In pernicious anæmia the value of splenectomy is doubtful, the improvement generally being no more than temporary. The operation should not be performed at an early stage of the disease. The results in leukæmia are also doubtful, and lately deep irradiation with X rays has seemed to offer better prospects in this disease. In Banti's disease a combination of splenectomy with Talma's operation is often desirable, with preliminary transfusion. In the treatment of all these blood diseases coöperation between surgeon and physician is very necessary.

PROCEEDS OF A HOSPITAL CARNIVAL.—The carnival held in June last on behalf of the Coventry and Warwickshire Hospital produced nearly £27,000. This sum includes a donation of £15,000 from Mr. W. R. Morris.

Correspondence.

"Audi alteram partem."

DUODENAL ULCER IN THE FEMALE.

To the Editor of THE LANCET.

SIR,—In your last issue is a most interesting paper on this subject by my friend, Prof. Wilkie, in which he deals chiefly with what he terms "the cholecystoduodenal syndrome." Though, as he says, "it is notorious that we only see what we look for," it may be allowed that Wilkie makes out a very good case for this syndrome, and he undoubtedly does a service in drawing attention to the symptom complex. I am not concerned, however, with this aspect of his paper, but my reason in writing to you is to draw attention to certain statistical points which he brings out, regarding (1) the relative frequency of gastric and duodenal ulcers in both sexes; and (2) the predominance of duodenal ulcers over gastric ulcers in both sexes. The figures he submits in each case are so closely in correspondence with figures of my own that I have thought it worthy of remark and of record.

My figures have been already submitted in two papers, the first published in your columns on April 7th, 1923, entitled a Statistical Inquiry into the Efficiency of Present-day Methods of Diagnosis of Ulcers of the Stomach and Duodenum, and into the Value of Gastro-jejunostomy in their Treatment, and the second, not yet published, delivered before the James Mackenzie Institute for Clinical Research about three weeks ago. The former of these papers dealt with two separate short series of cases. The latter paper was concerned with a more recent, somewhat larger series, purely of cases dealt with in my wards in the Western Infirmary, Glasgow. Wilkie's figures include, I understand, both hospital and private cases. The correspondence between his figures and mine is very striking, and, taken together, I think they may be taken as settling the proportions of these different ulcers in both sexes. Here they are.

Ratio of Gastric to Duodenal Ulcers.

Wilkie: 52 gastric ulcers, 310 duodenal ulcers ..	1 to 6
Young (three series combined): 30 gastric ulcers, 244 duodenal ulcers	1 to 8

Incidence of Gastric and Duodenal Ulcers in Both Sexes.

Wilkie: 22 gastric ulcers, 234 duodenal ulcers (Male sex.) ..	1 to 11 (approx.)
30 gastric ulcers, 76 duodenal ulcers (Female sex.)	1 to 2½
Young (last series): 10 gastric ulcers, 112 duodenal ulcers. (Male sex.)	1 to 11
8 gastric ulcers, 16 duodenal ulcers. (Female sex.)	1 to 2

In the light of these figures, it seems to me that it is justifiable to say that, in a case of gastric or duodenal ulcer, either chronic or perforated, and of doubtful location, the general as well as the sex incidence have a definite value in local diagnosis.

I am, Sir, yours faithfully,

ARCHIBALD YOUNG.

The University, Glasgow, Dec. 10th, 1927.

SURVIVAL AFTER OPERATION FOR BREAST CANCER.

To the Editor of THE LANCET.

SIR,—From the discussion at the Medical Society of London it appears that at the Cancer Hospital recurrence after the post-operative use of X rays has been "earlier and more rapid than in cases treated by surgery alone," and that no case has been cured by radium. Also at the West London Hospital no case has been "either improved or cured by X ray treatment." At the Middlesex Hospital may I say the results appear to be otherwise? Several primary cases have remained well with no signs of recurrence for three to five years after treatment by X rays or radium; in the post-operative group (mostly in Stage II. at operation) the three years' freedom from recurrence has been 47 per cent.—considerably more than percentages reported from the purely surgical treatment of similar groups of cases; and there l been a 22 per cent. three-year "cure" of ma recurrent cases.

I believe these differences must be due in la part at least to different radiological techniques. at the Cancer Hospital the very mild techni recommended by Dr. Robert Knox of applying "first dose along the line of the scar unfiltere ("Radio-therapeutics," 1918, p. 462) has been carr out, then there could not be easily devised a bet method of testing clinically whether there is o not a stimulating effect from X rays on any remain cancer cells lying deeper than the skin! The Vie school deny that there is clinically any stimulat dose of X rays, but Mr. W. E. Miles now bri forward apparently clinical evidence of its existen May it not be, however, that the stimulation i result of the operation? For I have seen seven eight cases which showed rapid widespread rec rences locally within a few months after operati to whom *no* radiation had been given, and these ca may be a clinical confirmation of the experimen finding that the best way to stimulate an ani tumour's growth is to cut into it. When surgery radiation are both employed is it not indeed diffi to estimate the comparative value of each?

Contrariwise to the Cancer Hospital techni (? insufficient dosage) the so-called "Erlange method used at the West London Hospital not o has not been used at Erlangen in post-operat work, but (unless special glancing methods are us intensive post-operative radiation in breast cases actually been found in several clinics to increase proportion of recurrences, owing to excessive gen effects.

How important technique is, in radiological a operative treatment, surely should not need to emphasised; but too often in discussions the poss variations in X ray and radium methods appea be forgotten in the estimation of results.

I hope soon to publish details of the observati and conclusions come to from over 500 cases breast cancer, treated with X rays or radium, already briefly reported at the Edinburgh meeting July.—I am, Sir, yours faithfully,

J. H. DOUGLAS WEBSTE

Chandos-street, Cavendish-square, W., Dec. 10th, 1927.

SIZE OF BRAIN AND MENTAL CAPACIT

To the Editor of THE LANCET.

SIR,—Regarding Dr. Bernard Hollander's comm on the relation between the size of the brain mental capacity, the following points may s worthy of consideration. The evolution of the m malian brain has essentially been an evolution of cerebral cortex. This has involved a multiplica of cortical neurons; this, again, has led both t increase in the thickness of the cortex and in extent of its surface; and this increasing surface necessitated a progressive increase in the size of brain. Now a big head has certain disadvanta not only does it involve an extra supply of nutrim and an extra powerful skeleto-muscular appar to support it, but it further predisposes to inj It being thus an advantage to limit, as far as sible, the size of the brain, the increasing exten the cerebral cortex has led to its being involute process which has enabled the surface of the co to be increased without increasing to a correspon degree the surface of the cerebrum as represente a cerebral cast.

During the evolution of the human brain from anthropoid phase there has been, as it were, a tinued attempt to limit, in the way indicated, increasing bulk of the brain necessitated by increasing superficies of the cortex. In some br this has been more successful—i.e., the involut are more numerous and deeper—than in oth It follows that the size of the brain is not an abs index of cortical extent. This is a fairly accu measure of cortical evolution; not, indeed,

rely accurate one, for, among other falsifying ors, the average thickness of the grey cortex is ter (and conceivably richer both as regards the ber and the complexity of the neurons it con- s) in some brains than in others. Hence the size ne brain is no certain index of the number (and plexity) of the neurons it contains. Broadly, the ber of cortical neurons is a fairly accurate index ental capacity, for their number has increased passu with the evolution of the vertebrate cere- n; and here let me incidentally record the nent fact that among mammals neurons, includ- hose of the cortex, do not multiply after birth, natter how strenuously they are thereafter exer- either by education or otherwise. Does not seem to dispose of the view that inheritance of tic acquisitions has been a factor in the evolu- of the mammalian cortex cerebri? Does it not definitely to prove that the increase in the ber of cortical neurons, which has accompanied been an essential part of that evolution, has n place by the natural selection of individuals ssing a super-average number of cortical neurons? ming now to observed facts, it would appear a distinctly small head more often goes along sub-average intelligence than a distinctly large goes along with super-average intelligence— while two out of three of the former class show verage intelligence, only one out of three of the class show super-average intelligence. If a clever person has a very small head, we may be ne has excellent cortical tissue, excellent inter- al connexions, a richly convoluted cortex, and cortical sulci. As a matter of fact, it is excep- to find clever men with small heads. Beacons- Gladstone, Salisbury, Rosebery, Campbell- rman, Balfour, Asquith, Lloyd George—all aded men—rose successively to the highest on in the State. In their case large brain and capacity manifestly went together.

Hollander referred to the emotional (as dis- shed from the intellectual) aspect of mind, ered in its relation to size of brain. So far as ns the cruder, more violent emotions, as dis- —e.g., in anger, fear, and the mating instinct— noteworthy that quite small masses of grey is tissue suffice to subserve them. One may s all these emotions powerfully displayed by birds with brains no bigger than a pea; and probably that our own strong emotions are ly subserved by quite a small mass of grey located in each of the thalami. The cortex pertains essentially to intellect.

I am, Sir, yours faithfully,

y-street, Dec. 10th, 1927. HARRY CAMPBELL.

THE TOXÆMIAS OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—My experience of medical cases and more lly mental derangement, which have arisen equel to a toxic condition during pregnancy s me to ask the favour of your columns to o the interesting monograph on the above recently published by Drs. J. N. Cruickshank, itt, and K. L. Couper, the research being con- under the ægis of the Medical Research Council. ef object is to ask a question and to make stion. The question is prompted by the fact to in your leading article on the subject in ue of Dec. 10th that the results of their instruc- l elaborate research had been largely negative as any fresh light on the problem was con- the main conclusion arrived at by the authors ummarised as follows: "If the toxæmias of cy have a common cause it is some form of tion by the break-down products of placental The possibility of an intestinal auto-intoxica- ng of ætiological importance is briefly referred is not seriously regarded, but the open mind uthors on the subject is shown by the state- nat "the importance of this factor in the production of toxæmia in the view of the Dublin school is shown by their insistence on colonic lavage as a means of treatment."

The report is based on the results of "a full clinical examination and a study of certain aspects of the chemistry of the blood and urine." In my view the existence of any potential or actual auto-intoxication has to be determined by the examination of the centrifugal deposit obtained from a carefully collected specimen of urine, attention being directed to the presence of bacteria and cellular constituents, and to the careful examination of the stools or a wash-out of the bowel, reliance being placed on the sound use of the unaided senses. No information under either of these heads is given in the valuable record of 200 cases investigated. To those who attach importance to the rôle of auto-intoxication as a factor of great importance in the ætiology of many chronic and acute diseases, information as to the state of the urine and stools in the series of cases would be of the greatest interest. My general experience leads me to think that in any series of 200 cases of toxæmia in pregnancy the examination of the urine would reveal a marked degree of bacteriuria in at least 90 per cent. of the cases, and the examination of the intestinal contents as voided would reveal unmistakable evidence of a high degree of abnormal putrefaction in every case. I think it probable that it is along these lines that we will ultimately find the common cause, if such exists.

I am strengthened in this opinion by the facts of comparative medicine. It is very rare to find any clinical evidence of toxæmia in pregnancy in the lower animals. I recently asked a capable and thoughtful stock-owner and breeder of very wide experience the secret of his great success in the management of his stock. His answer was instructive: I watch the skin and the droppings of my animals. The suggestion that I wish to make is the desirability of a further series of observations being made, in which attention is directed specifically to the two lines of inquiry referred to. The results could hardly fail to be of great interest and value. This research would have the merit of being one that could be very simply and effectively carried out, no high degree of laboratory training being essential.

I am, Sir, yours faithfully,

Edinburgh, Dec. 10th. CHALMERS WATSON, M.D.

ALKALI TREATMENT IN FEVERS.

To the Editor of THE LANCET.

SIR,—Dr. B. A. Peters in THE LANCET of Dec. 10th (p. 1232) refers to work of mine on the prevention of scarlatinal nephritis by the administration of alkalies by mouth. He presents figures to show that at his hospital 4000 odd cases were treated with alkalies and that the incidence of nephritis in these was the same as, or even a little higher than, in a similar number of untreated cases. The alkalies, however, were only given during the acute stage of the fever, usually about a week. It is scarcely necessary to point out that nephritis rarely occurs before the tenth day of the disease, that is, at a time when the cases referred to by Dr. Peters were not having alkalies, the figures he gives therefore being without value in this connexion. In fact, they merely show that the incidence of this complication was practically the same in the periods 1910–17 and 1918–27.

Repeated estimations of the alkali reserve have been made at intervals throughout the course of the disease in a large number of cases, and these show that a condition of acidosis (depletion of the alkali reserve) persists in the majority of cases for many weeks. It is for this reason that I have advocated the giving of alkalies in the later stages when nephritis is likely to occur. It is also probably because of this continued acidosis that symptoms of alkalosis have never yet been met with in now approximately 1000 cases treated with alkalies in the doses suggested. Incidentally, similar observations have been made of the alkali reserve in cases of scarlet fever having

throughout a vegetarian diet and on others having a high sugar diet. These figures will be published in due course. Dr. Peters notes that there were four cases of nephritis in my alkaline series, one ending in death, but he does not mention that in three of these cases the alkali had been omitted 48 hours before the nephritis occurred, or that in the fatal case the kidneys at autopsy showed microscopical evidence of an antecedent chronic nephritis.

Finally, I would like to take the opportunity of pointing out that I have only suggested the use of alkalies in scarlet fever for the prevention of nephritis and not as treatment for the primary disease.

I am, Sir, yours faithfully,

London, Dec. 11th, 1927. A. A. OSMAN.

THE TUBERCLE OF THE FIFTH METATARSAL.

To the Editor of THE LANCET.

SIR,—I should like to congratulate Mr. A. G. R. Foulerton and Dr. G. F. Stebbing on their very interesting paper on Fractures of Metatarsal Bones by Indirect Violence, with special reference to Avulsion Fracture of the Tubercle of the Fifth Metatarsal (THE LANCET, Dec. 10th, p. 1225).

May I at the same time point out that while they quote Testut and Grüber as having met only three cases in which the tubercle of the fifth metatarsal was a separate bone, in reality a separate ossific centre for the styloid of the fifth metatarsal occurs quite commonly. In radiograms of 50 subjects between the ages of 10 and 17 I found a styloid epiphysis present in 14 (28 per cent.), and in a paper on the subject, recently sent to the *Journal of Bone and Joint Surgery*, while speculating on the occurrence of this epiphysis I suggested that it may represent a traction epiphysis produced by the tendon of the peroneus brevis or possibly the abductor of the fifth metatarsal (Wood's muscle) frequently present in man.—I am, Sir, yours faithfully,

LAMBERT ROGERS,
Surgical Unit, Welsh National School of Medicine,
Dec. 12th, 1927. Royal Infirmary, Cardiff.

STATUS OF MENTAL NURSES.

To the Editor of THE LANCET.

SIR,—You commented last week on the meeting of the Royal Medico-Psychological Association at which this subject was considered. My own view may be stated thus. In any attempt to assess the comparative merits of the examinations of the Royal Medico-Psychological Association and the General Nursing Council for Mental Nurses, the following points deserve consideration: 1. Registration should give every nurse a national qualification and status. 2. The preliminary examination should be the same for all branches of nursing, so that a nurse can qualify in more than one branch without undergoing a test in practical elementary nursing more than once. 3. The devising and management of examinations for nurses should be in the hands of the nursing profession. The certificate of the Royal Medico-Psychological Association provides none of these things.—I am, Sir, yours faithfully,

H. WOLSELEY LEWIS,
Medical Superintendent, Kent County Mental
Dec. 12th, 1927. Hospital, Maidstone.

MERCUROCHROME INTRAVENOUSLY.

To the Editor of THE LANCET.

SIR,—Mr. Martindale's warning, under this heading in THE LANCET last week, is warranted. In "New and Non-Official Remedies," a volume in which are entered products approved by the Council on Pharmacy and Chemistry of the American Medical Association (and accepted by them for inclusion) there will often be found precepts of practical value to British practitioners.

I am, Sir, yours faithfully,

M.D.

MEDICINE AND THE LAW.

DAMAGES AGAINST A SURGEON.

AFTER conflicting evidence, a verdict was give the plaintiff in the case of Tyndall *v.* Alcock at Br Assizes in an action for damages for negli brought against a surgeon. A girl of 8 years o fell from a donkey in July, 1926, and fractured left arm. She was then taken 10 miles in a moto to Gloucester where she was treated by Dr. A Alcock, at first in a nursing-home and later in Gloucester Royal Infirmary. The case for plaintiff was that the arm became fixed at the e and, as the result of the development of Volkm contracture, movement was permanently impa Dr. H. Chitty, giving evidence for the plaintiff, that he examined the patient in October, 1926, found no voluntary movement of the wrist, fin and thumb; there was fixation and contracture as usually arose from tight bandaging or s pressure. Dr. Alcock, the defendant, gave evi that at his first examination he found a fractu the lower end of the humerus; the fragments in a bad position, the elbow slightly swollen, an ends of the bone injuring the tissues. He manipu the bones into position and a screen examin showed the fragments in alignment; he was sat that the fracture had been properly reduced. arm was then suspended from the shoulder an X ray photograph obtained. He stated—though was one of the facts in dispute—that he had fro first taken a serious view of the injury and h informed the girl's mother. The upper bony frag was almost through the skin and threatened s damage to other structures. He gave instru that the circulation should be carefully wat Next day the hand was slightly swollen an bandages were loosened. Four or five days there was more discoloration. He realised circulation was obstructed; the bandages loosened and the strapping removed. Three o days after the accident he suspected the possi of Volkmann's contracture; by the third we treatment he was sure of it. He knew the fra was slightly over-reduced, but he thought advisable since it involved less interference wit blood-vessels. Prof. Hey Groves, of Bristol, evidence for Dr. Alcock, as also did Dr. C. V. K (senior surgeon at the infirmary), the matron nursing-home, and a masseuse. Prof. Groves obs that the skiagram showed severe fracture o lower end of the humerus with satisfactory redu or over-reduction; if symptoms of Volkmann's tracture occurred, it was much more importa restore circulation than to restore alignment. thought Dr. Alcock had adopted the proper of treatment. Counsel for defendant submitte Dr. Alcock had not omitted any necessary ste had made radiological examinations in consul with a skilled radiologist. The jury, after an a of one and a half hours, returned a verdict th defendant had not properly set the bone an failed to treat the case properly afterwards. Justice Shearman refused to accept this, and, a fresh retirement, the jury found a verdict f plaintiff with £2000 damages and £150 for the m A stay of execution was granted on terms.

REDHILL HOSPITAL, EDGWARE.—Mr. N Chamberlain, the Minister of Health, last week open new Redhill Hospital, Edgware, which has been built Hendon Board of Guardians at a cost of £123,000. are at present 175 beds, but the accommodation extended in the future to provide for 500. In his Mr. Chamberlain pointed out that in the county of Mid the voluntary hospital accommodation, in proportion population, is considerably below the average for the of London, or even for the country. The new institu essentially for the treatment of acute medical and s cases.

Obituary.

JOHN PRIOR PURVIS, M.R.C.S. ENG.

WE have already briefly referred to the death of Dr. J. P. Purvis, which occurred at Greenwich on Nov. 18th, in his eighty-seventh year. He was the eldest son of the late Prior Purvis, M.D., of Blackheath, and was educated at Greenwich and at Blackheath Proprietary Schools. In 1859 he became a medical student on the *Dreadnought* hospital ship at Greenwich, afterwards proceeding to St. Thomas's Hospital, whence he graduated as L.S.A. and M.R.C.S. in 1863. For the next four years Dr. Purvis acted as house surgeon at the West Herts Infirmary at Hemel Hempstead, after which he began general practice at Greenwich as his father's partner. In 1869 he became medical officer to the Royal West Kent Dispensary (now the Miller General Hospital), and in 1885 he took up a similar appointment at the Greenwich Provident Dispensary, where he worked until his retirement two years ago. Like his father before him, Dr. Purvis was treasurer of the West Kent Medico-Chirurgical Society, having held that office since 1897. He was a keen Volunteer, serving as surgeon to the 2nd Volunteer Battalion of the Queen's own Royal West Kent Regiment, and was granted the volunteer decoration. For many years, also, he was lecturer for the St. John Ambulance Brigade, and he was appointed an honorary associate of the Order of St. John of Jerusalem. A public vaccinator since 1870, he was still engaged in this work four days before he died.

Dr. Purvis married in 1868 the elder daughter of the late Mr. William Vaughan, of Blackheath. He is survived by two of his five sons, and by both his daughters.

ALEXANDER ROBB, M.D., D.P.H. ABERD.

Dr. Alexander Robb, who died on Nov. 25th at his home in Corstorphine, had been since 1909 medical officer of health for the counties of Midlothian, West Lothian, and Peebles. Born at Cruden in 1870, he was the son of Mr. Andrew Robb, and was educated at the University of Aberdeen. After graduating with honours in 1895, he spent a short time in private practice before being appointed assistant medical officer to the county of Lanark, a post which he held until 1901. In that year he became medical officer of health for Paisley, where he induced the council to establish a municipal laboratory, chiefly for bacteriological work. Since 1909 he had been continuously at work in the Lothians, for during the war his services were retained for administrative purposes, and he had to take over the supervision of extra districts to relieve other medical officers.

Dr. Robb married a daughter of the late Mr. David McLardie, and she survives with one daughter.

ROBERT DUNSTAN, M.R.C.S. ENG.

Dr. Robert Dunstan, who died on Nov. 27th in his eightieth year, was by birth a Cornishman and for many years in practice at Plymouth and Ugnton. Educated privately and at Wadham House, Liskeard, he started his medical career as assistant to a local practitioner but afterwards went to London as a student of Guy's Hospital, qualifying L.S.A. in 1871 and M.R.C.S. in 1872. Among the appointments which he held at various times were those of medical officer to the Penzance rural, and of St. Ives urban, sanitary authorities, Admiralty surgeon under the Trinity Board, and medical officer in charge of troops at Paignton, where he settled in 1. Much of his professional life, however, was spent in London and of late he had lived in retirement at Brighton. Dr. Dunstan was at one time a well-known amateur chess player.

He was a widower and leaves two sons and two daughters.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

MENTAL DEFICIENCY BILL.

AT the close of a late sitting of the House of Commons in the early hours of Tuesday morning, Dec. 13th, the Mental Deficiency Act, which had been amended in Standing Committee, was considered on report. The Bill could only be taken at that hour if unopposed, and some objection being taken from the Labour benches it seemed at first that there was some danger of the measure being lost owing to the congested state of Parliamentary business at this period of the session. The Labour opposition, however, was not persisted in. On Clause 1 (which defines defective persons) Mr. B. CROMPTON WOOD, who was in charge of the Bill, moved two amendments to para. (*d*) of the clause, which were agreed to without discussion. As a result of these amendments para. (*d*) now reads as follows: "Moral defectives, that is to say, persons in whose case there exists mental defectiveness coupled with strongly vicious or criminal propensities and who require care, supervision, and control for the protection of others." The Bill was then read the third time, without discussion.

HOUSE OF LORDS.

THURSDAY, DEC. 8TH.

LANDLORD AND TENANT (NO. 2) BILL.

THE House went into Committee on the Landlord and Tenant (No. 2) Bill, the Earl of KINTORE in the chair.

On Clause 16 (holdings to which Part I. of the Bill applies),

Viscount SUMNER moved to amend the proviso at the end of the clause relating to improvements to premises used for carrying on a profession. He said that it was rather anomalous that this part of the Bill gave a benefit to people who carried on a trade or business, but declared that for the purpose of improvements of premises in which that trade or business was carried on, premises in which a profession was carried on "shall be deemed to be premises used for carrying on a trade or business." The form in which this was expressed was rather a reflection on those who carried on a profession, but nobody quite knew what a profession was. Nevertheless, the provision had a practical object, and he would like it to be as clear as possible. He did not think anyone could define a profession for the purposes of the Bill; at any rate, the Bill did not attempt a definition. Whether it was a professor of deportment, a professor of dancing, a professor of music, or a professor of occult science was a thing which the tribunal would be faced with; but so far as he knew, the principal premises in which a person could be properly carrying on a profession otherwise than in offices were those which he proposed to mention at the end of the clause so as to clear the matter up. The proviso would then read:—

"Provided that so far as this part of this Act relates to improvements, premises used for carrying on the profession of a qualified physician, surgeon, solicitor, notary public or architect, shall be deemed to be premises used for carrying on a trade or business."

There was a practice by which in the country solicitors and notaries and architects carried on their profession, a genuine profession, in the house in which they lived, and of course, physicians and surgeons constantly did so. It appeared to him that if those persons, if duly qualified, were declared to be the professional men for whose protection this subsection was introduced, it would prevent claims and sometimes expensive and perhaps doubtful discussions before the tribunal as to the persons whom the clause was really intended to benefit.

Viscount BERTIE OF THAME: Can the noble viscount tell me why he has omitted dentists?

Viscount SUMNER: Because I did not think of it.

Viscount BURNHAM said he thought it would be very unwise to adopt a narrowing and restrictive amendment of this sort. *Expressio unius est exclusio alterius.* It meant that all these multifarious professions which had a genuine goodwill attaching to the premises in which the profession was carried on, and in which improvements were made for the purpose of carrying on the profession, would be left out of the Bill. In the East End of London there were many doctors who had consulting-rooms which were really in the nature of shop premises. At some time they had actually been shops, and had been added to and made more convenient for the practice of the profession. Dentists were in exactly the same category, and it would be most unwise, without further consideration, to state that some kinds of professions, or some professional callings, came under this heading by the adoption of words of this sort.

Once adopted these words would limit the right to compensation to the particular classes specified in the Bill.

Viscount SUMNER said that he accepted "dentist," but he entirely rejected "specialist."

Lord DANESFORT said that he agreed that the word "specialist" was a very vague one. There was no definition of it in the Bill, and it would be extremely undesirable that a man who wanted to claim compensation for improvements should have to go through an expensive law suit to see whether he was a specialist within the meaning of the Bill. He urged the Lord Chancellor to accept the amendment, and, if before the report stage there appeared to be any other legitimate professions which ought to be inserted in this clause, it would be possible to include them.

Lord JESSEL thought that it would be very difficult to limit the classes. In London they saw advertisements of dancing mistresses in the newspapers. That was a profession, and the improvement of their rooms was of great moment to them. How were they going to omit them if they admitted dentists? They had also left out veterinary surgeons. It would be better to leave it alone and not create another class of privileged person. People should be left to fight it out.

The LORD CHANCELLOR said that with great deference to Lord Sumner he thought it would be better not to try to insert a list of these professions. Already they had had suggested the dentist, the teacher of dancing, the veterinary surgeon, the bone-setter, the engineer, who had just as much right as the architect and the surveyor. If they went on thinking they would find other categories that ought to be added.

Viscount SUMNER said that it was obvious that he could not press the matter, but he said quite seriously that their lordships were deliberately opening a door to a large amount of ridiculous litigation by persons who were entitled to say that they were as good professional people as solicitors or architects or dentists. The whole sentiment of the Bill was in favour of the claimant, and they would find that persons were getting compensation for their improvements who were persons never contemplated by those who framed the Bill. He asked leave to withdraw the amendment.

The amendment was, by leave, withdrawn.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 7TH.

International Maternity Convention.

Mr. ROBERT YOUNG asked the Minister of Labour whether, now that the Government of the German Reich had ratified the International Labour Office Convention on maternity protection, he would expedite its ratification by His Majesty's Government.—Sir ARTHUR STEEL-MAITLAND replied: The general reason which led His Majesty's Government delegates at Washington in 1919 to abstain from voting for the adoption of the maternity convention, and which led successive governments to refuse to ratify, are that, in the British view, the benefits provided under the health insurance scheme and other social services already in operation in this country are in accordance with the policy of the convention and are, indeed, in some respects in advance of those embodied in the convention.

Mr. YOUNG: Is the right hon. gentleman not aware that the maternity mortality has not decreased in this country during the past 15 years, and is not that a reason for ratification of the convention?—Sir A. STEEL-MAITLAND: I will communicate the first part of the question to the Ministry of Health. As regards ratification of the convention this country has already in force a policy aiming at the same results and it was considered that the adoption of the specific proposals made in the convention would lead to serious administrative difficulties, and that the benefits which might be so conferred would be restricted to a more limited class.

Agriculturalists and Health Insurance.

Mr. DIXEY asked the Minister of Health whether he is aware of the fact that there was a general desire among agriculturalists to have a separate health insurance scheme for the industry; and, if so, would he consider the matter.—Sir KINGSLEY WOOD replied: The answer to the first question is in the negative. As regards the second, I may remind the hon. Member that under the present general scheme of National Health Insurance it is open to persons employed in agriculture to form approved societies of their own and thus to secure to themselves the full advantage of the contributions payable by and in respect of them. A number of such special agricultural and rural societies have, in fact, been formed and are administering the scheme with favourable results to their members.

Old Age Pensioners and Sickness Benefit.

Mr. CONNOLLY asked the Minister of Health whether an insured person who was in receipt of full sickness benefit under the National Health Insurance Act, on attaining the age of 65 years, or under the 1908 Act at 70 years would be compelled to give up sickness benefit and appl for the old age pension.—Mr. CHAMBERLAIN replied: Up t the present time the position has been that an insure person's right to sickness or disablement benefit has cease on his attaining the age of 70. Under a provision of th Widows', Orphans', and Old Age Contributory Pension Act, 1925, the right to these benefits will cease at age 6 in all cases as from Jan. 2nd next, after which date old ag pensions will be payable to persons aged between 65 and 7 who are duly qualified.

Complaints against a Public Vaccinator.

Mr. BROAD asked the Minister of Health whether he wa aware that Dr. Pearson, medical officer to the Buckingha institution and public vaccinator for the Leckhampstea district of the Buckingham union, called on Mrs. Rodwel of Chackmore, on Tuesday, Sept. 20th, and demanded tha her five children, whose ages ranged from 19 years t 8 years, and who had been exempted by their father fro vaccination, should be vaccinated, on account of two cas of small-pox that had been found at the Buckingha institution, situated a mile and a half away from Mr Rodwell's home; that Mrs. Rodwell told Dr. Pearson tha the children would not be vaccinated on account of h husband's strong objection to the operation, the fath being at the time kept in isolation at the institution; tha Dr. Pearson threatened to have the post office, kept b Mrs. Rodwell, closed if she and the children were n vaccinated, and also to stop the boys from working unle they agreed to be vaccinated; that Mrs. Rodwell gav way and had herself and the children vaccinated in th unwarranted belief that Dr. Pearson had power to clo the post office; whether he would point out to Dr. Pearso that in his capacity of public vaccinator his duty consist in offering to vaccinate children who were neither exempt nor vaccinated, and that he had no right to threaten objecto to the operation; and what fee Dr. Pearson received f the vaccination of Mr. Rodwell's children and Mrs. Rodwe —Mr. CHAMBERLAIN replied: I have made inquiries regard to this matter, and am informed that the followi are the facts: Dr. Pearson called on Mrs. Rodwell ar offered to vaccinate her and her children because they ha been in contact with her husband, who was employed at t Poor-law institute where cases of small-pox had occurre An elder daughter, who had returned to the house for tha purpose, expressed willingness to be vaccinated. Mr Rodwell at first demurred to the vaccination of hers and a younger child, and Dr. Pearson suggested that s should telephone to the institute and obtain Mr. Rodwell permission. This she declined to do, but, on being inform by Dr. Pearson the her husband was being vaccinated, s consented to the vaccination of herself and the younge child. Three other members of the family went to D Pearson's surgery and were vaccinated. Dr. Pearson w not informed that declarations of conscientious objecti had been made in respect of the children. He told Mr Rodwell that, having regard to the fact that she kept post office, she should be vaccinated, as otherwise he fe it would be his duty to inform the authorities, but he deni having used any threats. There does not appear, therefor to be any reason for taking the action suggested by t hon. Member. The doctor's fee for which the guardians a liable, for the vaccination of Mrs. Rodwell and her childre amounts to 22*s*.

Houses Built Since the War.

Mr. POTTS asked the Minister of Health the total numb of recorded dwelling-houses actually built and tenant for the years 1914 to 1926, inclusive, for England a Wales.—Sir KINGSLEY WOOD replied: The informati desired by the hon. Member is not available, but the numb of houses erected from the Armistice to March, 1927, w approximately 866,500.

THURSDAY, DEC. 8TH.

Reform of Penal Methods.

Sir JOHN POWER asked the Home Secretary wheth he contemplated any changes in the penal methods appli to habitual criminals.—Sir W. JOYNSON-HICKS replied: T matter is always in my thoughts, but no change of importan can be made until after exhaustive inquiry.

Open-air Schools in Mining Areas.

Mr. BARKER asked the President of the Board of Educati if he was prepared to issue to local education authoriti a special instruction to take immediate steps to provi the necessary open-air school accommodation for t increasing number of children in the mining areas wh by reason of the distress prevailing, were suffering fro latent tuberculosis, debility, and anæmia; and would consider whether the emergency called for special organis tion on behalf of the child sufferers from industrial depressio

Lord EUSTACE PERCY replied: In regard to the general estion of open-air schools, I would refer the hon. Member to e answer which I gave him on Feb. 17th last. I am inclined doubt whether the effect of the industrial depression mining areas on the health of the children has been as rious or as general as the hon. Member suggests, and ether any ill-health which does exist can be dealt with the provision of open-air school accommodation, but am taking steps to have a special inquiry made by one the Board's medical officers into the whole situation in uth Wales.

Position of the Voluntary Hospitals.

Mr. LUNN asked the Minister of Health what was the tal number of beds provided in voluntary hospitals roughout the country on Dec. 31st, 1925, and what was e number to-day; what was the financial position of luntary hospitals in the aggregate at the latest date of ich he had information; and what powers had the Cave mmittee to mitigate the financial difficulties of these spitals.—Mr. CHAMBERLAIN replied: I have no official ures showing the position at the end of 1925, but the rvey carried out by the Voluntary Hospitals Commission owed a total of 50,460 beds in voluntary hospitals in gland and Wales at the end of June, 1924. On the best ormation at my disposal the corresponding figure at c. 31st, 1926, was 54,406 beds, or an increase in the erval of two and a half years of 3946 beds. As regards the ond part of the question, according to the reports of ng Edward's Hospital Fund and of the Red Cross Society, London hospitals showed an aggregate deficit of £39,000 1926, and the rest of England and Wales showed an gregate surplus of £286,000, the combined figures giving iet surplus of £247,000 for the whole of England and les. As regards the third part of the question, Lord ve's Committee completed their inquiry six years ago. he hon. Member is referring to the Voluntary Hospitals nmission, the answer is that the Commission have eady distributed the full amount voted by Parliament, they have no funds now at their disposal. The figures ave given are sufficient to show that the financial position the voluntary hospitals generally has greatly improved e Lord Cave's Committee issued their report in 1921.

Preservatives in Dairy Produce.

ieut.-Colonel RUGGLES-BRISE asked the Minister of lth the nature of the preservatives most commonly d in the imports into this country of dairy produce, cially as regards the following articles: butter, cheese, m, liquid milk, and condensed milk.—Mr. CHAMBERLAIN ied: Preservatives are not now allowed in any dairy luce, whether imported or produced in this country, pt butter and cream, and the prohibition will apply to e articles also on Jan. 1st next. I am informed that, n butter or cream contains preservatives, the substance is usually a preparation of boric acid.

Cost of Inmates in Poor-law Institutions.

r. RITSON asked the Minister of Health whether he ld state for the latest convenient date the average per head per week of persons maintained on indoor f in Poor-law institutions; and the most frequent rate harge per head per week for pauper inmates in county tal hospitals.—Mr. CHAMBERLAIN replied: The average rly cost per head for the year ended March 31st, 1926, ding the cost of buildings and loan charges, of the ons maintained in Poor-law institutions in England Wales, was 27*s.* 8*d.* The rate of charge per head per for pauper inmates in county mental hospitals would oximate to 22*s.* 6*d.*

Human Beings and Foot-and-Mouth Disease.

. VERNON DAVIES asked the Minister of Health if he any evidence of any cases of foot-and-mouth disease man beings during recent years; and, if so, would ve details of such cases, showing the source of infection he result of each case.—Mr. CHAMBERLAIN replied: So s I am aware no case of foot-and-mouth disease in a an being has occurred in this country in recent years. only two cases of suspected foot-and-mouth disease of I have any record were investigated by a medical r of my department and in neither case could any rmation, either clinical or biological, be found to support suggestion that the patient was suffering from this se.

Health Conditions in Offices.

ut.-Colonel FREMANTLE asked the Minister of Health view of the health conditions prevailing in many s, he was satisfied that the inspection of offices at nt carried on, and the powers of local sanitary authori- London and elsewhere, were sufficient for the purpose. . CHAMBERLAIN replied: I have no evidence that the h conditions generally prevailing in offices are such as ll for special action. The present powers of local authorities in the matter have not been shown to be insufficient, but the measure of inspection at the present time cannot but be conditioned by financial circumstances.

Lieut.-Colonel FREMANTLE: Is it not a fact that health rates and sickness rates in offices are worse than among the general population and therefore justify inspection and inquiry?—Mr. CHAMBERLAIN: I have no evidence of that.

Lieut.-Colonel FREMANTLE: If I give the right hon. gentleman that evidence, will he look into it in conjunction with the Standing Joint Committee of the Metropolitan Boroughs, who have had this matter under consideration for a long time?—Mr. CHAMBERLAIN: I shall certainly be glad to consider any evidence which my hon. friend produces.

Death-rates from Tuberculosis.

Mr. HORE-BELISHA asked the Minister of Health what was the mortality during the last five years of persons suffering from tuberculosis.—Mr. CHAMBERLAIN replied: The crude death-rate in England and Wales from all forms of tuberculosis for the years 1922 to 1926 were, respectively, 1121, 1062, 1058, 1038, and 961 per 1,000,000 persons living.

Adulteration of Food.

Major AINSWORTH asked the Minister of Health whether, in view of the fact that in 1926–27 his department, in examining samples of liquid eggs, found that one-third of the quantity were either adulterated or not up to standard, and that in 1926 28,600 tons of this article were imported into this country of which 9533 tons might be proportionately regarded as equally unsatisfactory, he proposed to make further investigation to prevent the influx of such material which was not up to the proper standard of good human food.—Mr. CHAMBERLAIN replied: I understand that some, if not all, of the samples of liquid egg which were reported against by the public analysts in 1926 were regarded as adulterated by reason of the presence of an excessive amount of boric acid preservative. The complete prohibition under the Preservatives Regulations of the presence of any preservative in egg-yolk and articles prepared therefrom takes effect on Jan. 1st next, and as these regulations apply to importation as well as sale, it may be expected that further cases of such adulteration will not occur.

Diphtheria and the Schick Test.

Mr. DAY asked the Minister of Health whether the officials of his department had come to any decision for the purpose of recommending to the health authorities of England and Wales the Schick test and immunisation methods for the prevention of diphtheria; and what progress had been made.—Mr. CHAMBERLAIN replied: I am advised that this method of protection against diphtheria is one of proved utility. The evidence collected in regard to it has been made available to the local health authorities in reports from my department, notably in the last Annual Report of the Chief Medical Officer (1926, pp. 52–53), as well as in a Report on the Prevention of Diphtheria issued by the Medical Research Council during the present year (M.R.C. Report 115). The official memorandum issued by my department on this subject in 1922 is now being revised, and the new edition will re-indicate the action which it is open to local health authorities to take in the promotion and the use of this method of protection, and the assistance which they may obtain for this purpose from the Ministry of Health.

Road Fund Grants to Hospitals.

Mr. NAYLOR asked the Minister of Transport whether, in view of the pressure upon hospital accommodation and treatment caused by the number of motoring accidents, he would consider the desirability of obtaining power to make grants from the Road Fund for the purpose of enabling such hospitals to meet the extra costs so incurred.—Colonel W. ASHLEY replied: I do not think that contributions of the nature suggested by the hon. Member could properly be made from the Road Fund, in view of the purposes for which that Fund was instituted.

MONDAY, DEC. 12TH.

South American Meat and Foot-and-Mouth Disease.

Mr. CRAWFURD asked the Minister of Agriculture whether, seeing that the chief veterinary surgeon of the Ministry of Agriculture had been in South America since last April investigating the whole system of dealing with the export of beasts to this country, and that it was now proposed that the Parliamentary Secretary to the Ministry should now join him there, why it was necessary for the Parliamentary Secretary to go to South America instead of the chief veterinary surgeon being brought back to report; whether he could state the nature of the negotiations the Parliamentary Secretary was to conclude with the South American authorities; how long he would be absent; and what was the estimated cost of his visit.—Mr. GUINNESS replied: In March the Ministry asked three of the Governments of the

countries in South America which export meat to this country to accept certain proposals which were designed to prevent the introduction of the virus of foot-and-mouth disease into Great Britain. With the consent of these Governments, Mr. Frood, a senior veterinary inspector of the Ministry (not the chief veterinary officer) was sent to South America more fully to explain these proposals to the Governments concerned, and to collaborate with them in adapting them to local conditions. Mr. Frood has been given every facility to study the disease position, and reports that he has reason to believe that the Governments of the South American countries concerned will find a way to give effect to the Ministry's suggestions. The Parliamentary Secretary, who is going on a pleasure cruise to Rio de Janeiro, will extend his voyage to confer with representatives of the Argentine and Uruguayan Governments and Mr. Frood, in the hope of completing the negotiations in relation to measures for the control of animal diseases which these countries propose to adopt with a view to removing risk of transmission of foot-and-mouth disease to this country. He will be absent for about seven weeks altogether. The estimated cost to the Ministry is £50.

Dr. VERNON DAVIES asked if any meat contaminated with foot-and-mouth disease had been brought in from South America at any time?—Mr. GUINNESS: We have no evidence of that.

Medical Officers of Health.

Dr. VERNON DAVIES asked the Minister of Health the number of urban district authorities in England and Wales with full-time medical officers of health.—Sir KINGSLEY WOOD replied: There are 118 non-county boroughs and 182 urban districts in England and Wales with full-time medical officers of health.

Grants to Voluntary Hospitals.

Mr. THOMAS WILLIAMS asked the Minister of Health if he was aware of the great deficiency in the number of beds in the voluntary hospitals of Great Britain; that this deficiency was largely due to lack of funds; and would he consider the advisability of making grants towards capital expenditure in approved cases on the lines indicated in the Onslow Report.—Sir KINGSLEY WOOD (Parliamentary Secretary) to the Ministry of Health, replied: My right hon. friend is glad to say that the deficiency in beds reported by the Voluntary Hospitals Commission has been materially reduced since their survey in 1924. In view of the financial position of the country, my right hon. friend did not at that time feel justified in recommending a grant from public funds in aid of capital expenditure, and the progress made from purely voluntary sources since that date has been so encouraging that he sees no ground for considering the question again.

Imperial Research Grants.

Mr. ORMSBY-GORE (Under Secretary for the Colonies), in reply to Mr. BLUNDELL, stated that in making grants for scientific research the Empire Marketing Board aimed at supporting schemes which promised to benefit either the Empire as a whole or, at any rate, more than one part of it. An apportionment of expenditure must to a large extent be arbitrary in the field of scientific research and economic investigation. The principal grants made or approved by the Board during the first 18 months of its operation included: £50,000 to the Australian Government for the establishment in Northern Australia of a Tropical Research Station; £9000 to the Liverpool School of Tropical Medicine for research in metazoan immunity; £1500 to the Department of Scientific and Industrial Research for research into the preservation and transport of fish; and £1000 for the transport of Irish Free State butter; £20,000 to the Medical Research Council for research work at the Lister Institute on the vitamin content of fruit, vegetables, and dairy produce; and £6000 to the Rowett Research Institute, Aberdeen, for research into the physiological and pathological conditions associated with certain rationed and specialised diets, with special reference to Kenya native tribes.

Medical Tests of Civil Service Candidates.

Mr. HORE-BELISHA asked the Secretary to the Treasury whether it was the practice of the Civil Service for medical tests of candidates to be made subsequent to their passing examinations for Government appointments; and whether, seeing that a number of successful candidates, who had spent money and time in preparation for these examinations, were disqualified for selection owing to failure to pass the medical tests, he would consider the possibility of making arrangements for candidates to be medically examined before they embarked on their preparation for the educational examinations.—Mr. A. M. SAMUEL replied: It is not the practice of the Civil Service Commissioners to examine the physical qualifications of persons who apply for admission to Civil Service examinations. Their physical eligibility for appointment is investigated in the event of their success. The number of candidates unsuccessful at an examination is normally much greater than the number of those who ... successful. The medical examination of all applica... would put the majority to unnecessary expense in paym... of medical examiner's fees, and would involve an expens... and unprofitable addition to the work of the Civil Serv... Commission. The Commissioners issue a memorand... for the guidance of intending candidates, setting out physi... qualifications of importance, and recommending intend... candidates, who are in doubt as to their eligibility, to ... examined by their own medical advisers before they be... preparation for a competition.

Definition of Miners' Nystagmus.

Sir RICHARD LUCE asked the Home Secretary whet... any conclusion had yet been come to in the matter ... establishing a more satisfactory definition of min... nystagmus; and whether he was aware that the pres... definition was differently interpreted by different ophthalm... surgeons and made it difficult for the medical referees ... give equitable decisions in many cases.—Sir W. JOYNS... HICKS replied: I fully realise the unsatisfactoriness of ... present position, but the matter is one of very considera... difficulty, and I have found it necessary to refer again ... the Medical Research Council for further advice on cert... points. I regret, therefore, it is not yet possible to co... to a final decision.

TUESDAY, DEC. 13TH.

Infection from Discharged Sanatorium Patients.

Mr. HORE-BELISHA asked the Minister of Health whet... his department had any scheme under consideration ... prevent the spread of infection of tuberculosis by dischar... sanatorium patients.—Sir KINGSLEY WOOD replied: It i... the duty of the local medical officer of health under ... Tuberculosis Regulations to take such steps as are necess... or desirable to prevent the spread of infection in every ... of tuberculosis which is notified to him, and those pati... who receive sanatorium treatment are instructed in ... precautions necessary to avoid the risk of infecting ot... persons.

Mr. HORE-BELISHA asked if Sir Kingsley Wood ... aware that it was customary for ex-sanatorium patient... be sent back in a very bad condition, and that they develo... the disease again and spread it?—Sir KINGSLEY WOOD s... that one could not dispose of the matter in that way. ... a number of cases these unfortunate people returned ho... of their own desire, or sometimes at the request of t... relatives. It was very difficult indeed to deal with such ca...

Dr. VERNON DAVIES asked if Sir Kingsley Wood ... satisfied that the local authorities were doing all in t... power to deal with these cases.—Sir KINGSLEY WOOD: ... I am never satisfied in these matters.

After-care of Tuberculous Patients.

Mr. HORE-BELISHA asked the Minister of Health w... percentage of tuberculous cases, discharged after treatm... from sanatoria, died from tuberculosis within five year... their discharge, and whether his department had u... consideration any schemes for the after-care of patients ... had been treated in sanatoria for tuberculosis.—Sir KINGS... WOOD replied: My right hon. friend regrets that ... information asked for in the first part of the question is ... available. As regard the second part, local authorities ... empowered under the Public Health (Tuberculosis) ... 1921, to make arrangements for the after-care of per... who have suffered from tuberculosis, and many ... authorities have made arrangements of this kind.

Mr. HORE-BELISHA asked if Sir Kingsley Wood was a... that his department did not appear to keep any of ... really valuable statistics relating to this illness, and i... would take steps to see that more accurate informa... was collected so that it might be available.—Sir KINGS... WOOD replied that the hon. Member was under a misap... hension. He would be glad to show him the statistics ... department had, and explain to him the many steps ... they were taking in the matter.

HOSPITAL ASSESSMENTS.—Under the revalua... just completed in virtue of the new Rating and Valua... Act, the assessments to local rates of the Brighton Hos... have been greatly increased. That of the Royal Su... County has been raised from £64 to £3375; of the Childr... Hospital from £48 to £1144; of the Women's Hos... from £96 to £490; of the Throat and Ear Hospital from ... to £450; of the Eye Hospital from £24 to £300. Hith... hospitals have usually been arbitrarily assessed on a ... scale, but the new Act is designed to secure all-r... uniformity. The powers of the Minister of Health u... the measure are, however, so extensive that it is beli... to be within his competence to authorise the special as... ment of hospitals and other charitable institutions.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At e Final Fellowship Examination, held from Nov. 17th to ec. 1st, for which 114 candidates presented themselves, candidates were approved. Six candidates, J. C. B. len (St. Bart.'s), J. T. Fathi (London), J. Gore (London), L. Holt (Manchester), H. J. Seddon (St. Bart.'s), and M. Walker (Univ. Coll.), although successful at the amination, are not eligible for their diploma on account age. The following are the names and medical schools the successful candidates :—

J. P. Ainslie, Melbourne and Guy's ; F. C. Alton, St. Thomas's and Guy's ; E. T. Bailey, Middlesex ; B. Biggar, St. Bart.'s and Guy's ; P. D. Braddon, Sydney and St. Bart.'s ; W. H. Bremner, Otago and Guy's ; R. Broomhead, Leeds and St. Bart.'s ; R. K. Debenham, Cambridge and London ; A. A. Digges la Touche, Cambridge and Leeds ; S. W. Drinkwater, Manchester ; A. S. El-Katib, Cairo and St. Thomas's ; D. J. Evans, Birmingham and St. Bart.'s ; A. W. Fawcett, Edinburgh, Sheffield, and Guy's ; J. Fitzsimons, Otago and Guy's ; F. N. Foster, Leeds and Guy's ; E. A. Freeman, St. Bart.'s ; A. T. Fripp, Oxford and Guy's ; W. D. Galloway, Cambridge and Guy's ; W. H. George, Cardiff and London ; J. F. Hackwood, St. Thomas's ; C. H. Hembrow, Melbourne and London ; J. H. F. Jayasuriya, Ceylon and St. Bart.'s ; B. G. Johnston, Adelaide and London ; E. S. J. King, Melbourne and Middlesex ; C. H. G. Macafee, Belfast ; J. McFadzean, Glasgow and London ; S. M. Milner, Cambridge, Manchester, and St. Bart.'s ; E. D. Moir, St. Bart.'s ; W. M. Robb, Edinburgh and St. Bart.'s ; J. E. Schofield, Sheffield ; N. A. Sprott, Oxford and St. Thomas's ; and J. M. Weddell, Cambridge and St. Bart.'s.

Diplomas of Member were conferred upon the following :— . S. Davies, Oxford and Guy's ; C. R. Greene, Oxford and Westminster ; and Alison R. Kerridge, Royal Free.

licences in Dental Surgery were conferred upon the owing 46 candidates :—

C. Allen, T. J. Barnes, F. R. Bate, M. Bengis, M. G. Berry, V. G. Boyle, Josephine A. Bradley, D. C. Buckley, T. M. Calhaem, R. Catchpole, H. E. S. Collingwood, N. H. Cove, Mary P. Davies, F. W. K. Duncan, S. Edwards, G. A. Evans, E. H. Fenton, L. M. Garrett, A. J. K. Geere, J. W. Gilbert, H. Gordon, E. T. B. Graham-Scott, Tatiana P. Guercken, F. E. D. Hallon, L. J. Haworth, A. H. Herbert, H. Herzenberg, C. Himmelhoch, W. Holgate, G. K. Lacey, B. F. Mahony, C. F. L. Purslow, S. A. Quarterman, N. L. Salton, H. T. E. Sly, E. C. Smith, H. W. Spreadbury, C. N. Talmadge, G. G. Thwaits, C. A. E. Tomes, P. S. Turner, G. N. S. Weller, D. R. A. Wilcox, J. E. Willett, R. G. Woodward, and L. A. Wyborn.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS GLASGOW.—At the monthly meeting of the Faculty, on Dec. 5th, the following were admitted (after examion) as Fellows : Andrew Naismith Fergus, Shaikh . Faruki, and James Edwin Stanley Lee. The Macewen al, presented to the Faculty by Mr. J. A. C. Macewen, emory of his father, the late Sir William Macewen, was ded to William C. McLaren, the most distinguished nt in surgery of the year who had passed the examina- of the Scottish Conjoint Board, and who had obtained linical instruction in surgery in Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.— following are the Council and office-bearers for the ng year :—President, Dr. Robert A. Fleming ; Vicedent, Dr. George M. Robertson ; Council, Dr. G. Lovell nd, Dr. Robert Thin, Dr. John Orr, Dr. William yce, and Dr. Edwin Matthew ; treasurer, Sir Norman er ; secretary and registrar, Dr. George Gibson ; rary librarian, Dr. Robert Thin ; curator of the labora- Sir Robert Philip ; representative of the General cal Council, Dr. William Russell : superintendent of aboratory, Lieut.-Colonel McKendrick ; librarian, Mr. . Graham.

ENCEPHALITIS AFTER VACCINATION IN HOLLAND.— he request of the Minister of Labour the President of Dutch Public Health Council has formed a committee vestigate the occurrence of the nervous sequelæ of nation to which we again drew attention last week LANCET, Dec. 10th, p. 1249). According to the *erlandsch Tijdschrift voor Geneeskunde* of Dec. 10th, the mittee consists of Dr. N. M. Josephus Jitta (President), H. Aldershoff, Dr. J. P. Bijl, Prof. L. Booman, Dr. van Bouwdijk Bastiaanse, Dr. H. S. Frenkel, Prof. n Logbem, Dr. J. T. Terburgh, and Dr. A. J. Vitringa. subcommittees have been formed to discuss the ing aspects of the question : (1) ætiology, pathology, reatment ; (2) epidemiology and organisation of proxis ; (3) the characters and varieties of vaccine lymph. Public Health Council invites the Dutch medical sion to help the committee by supplying medical s of health with full details of any cases occurring in practice.

Dr. William Henry Davison has been appointed coroner for the City of Birmingham.

ROYAL SOCIETY OF MEDICINE.—The Society's house will be closed for Christmas from Friday, Dec. 23rd to Tuesday, Dec. 27th, inclusive.

HOSPITAL SAVING ASSOCIATION.—Lord Cave, the Lord Chancellor, presided recently at the fifth annual general meeting of this Association, which was attended by some 2000 workers for the hospitals. There are now 351,000 members, an increase of 84,794 in the last 12 months, a number estimated at about 12 per cent. of the hospital population of Greater London. The total of wage-earners' contributions, based on a weekly payment of threepence per head, was £179,759, as against £128,762 in 1926. Payments for hospital services to members have risen from £83,926 last year to £127,196, and during the Association's year, which ended on July 31st, 99,754 contributors and their dependants were treated at voluntary hospitals. At the meeting speeches were made, among others, by "a business girl," a policeman, and a tramwayman.

EPSOMIAN CLUB DINNER.—The annual meeting and dinner of the Old Epsomian Club, which was held at the Trocadero, London, on Dec. 8th, was regarded as the club's jubilee, for it was the fiftieth meeting since Epsomians first dined together at the Cannon-street Hotel on July 13th, 1868, prior to the inauguration of the Propert Memorial Fund. The chair was taken by the new President of the club, Sir Cecil Armitage, lately Governor of Gambia and well known as an African explorer, who spoke of the wonderful opening for young medical men in West Africa. He related some of his adventures in the Colonial Medical Service, saying that the longer he remained in West Africa the more he became a sort of fetish to the natives. The headmaster, Mr. A. C. Powell, in responding to the toast "Floreat Epsomia," recounted the academic and athletic progress of the past year : 64 boys entered for the school certificate, of whom 59 obtained it, and he regarded the Rugby XV. as equal to that of any public school in the country. He remarked on the steady shift in the age-grouping of the school since the entrance age had been raised from 8 to 12 years. In 1922, out of 319 boys, 234 were of public-school age ; this year, out of 389 boys, 329 are of public-school age ; and by 1930 no doubt the number would have risen to 400. He was glad to welcome at the dinner their grand old man, Mr. Smith Pearce, a former headmaster, and from the present school the head prefect and the captain of football. Dr. H. F. Ealand proposed "The Guests" in a very humorous way, and Mr. Ormsby-Gore, M.P., Parliamentary Under Secretary for the Colonies, responded. He paid a high tribute to the medical men who go overseas and carry there the public school tradition. In Africa, he said, we badly want men trained in veterinary as in medical science. Progress languished because biologists and entomologists with the necessary knowledge could not be found, and he appealed for a generous allotment of time to biology in the school curriculum. Mr. G. E. Pinchard proposed "The President," who, in replying, mentioned the presence of the veteran Dr. Beckingsale, one of the first boys to enter the school.

CANCER RESEARCH IN IRELAND.—The Council of the National Cancer Campaign (Ireland) has issued a statement on its objects and scope. The Council is made up of representatives of universities, the Royal Colleges, and scientific societies, together with nominees of the Royal City of Dublin Hospital and of the joint committee of the British Red Cross Society and the Order of St. John. Its aim is twofold—research and education. It is hoped to collate and analyse the results of different forms of treatment carried out in the several hospitals of Ireland. At the same time attention will be paid to the study of causes, and clinical work in this connexion can be carried out at any hospital, members of whose staff are willing to collaborate with the workers of the campaign. The experimental part of the research will, in the first instance, be carried on at 14, Upper Baggot-street, Dublin, under the direction of an expert director, and under the supervision of a member of the Council who has accepted the post of honorary director. But, as funds permit, it is hoped to assist workers in other laboratories. As regards education, it is the intention of the Council to attempt to awaken the public as to the danger of cancer to the community, to convince them of the need of research, and to teach them, as far as is possible, how to recognise the first signs of the disease. The success attained by a similar campaign against tuberculosis some 20 years ago encourages those engaged in the present campaign. In conclusion, it should be made clear that the campaign is neither in constitution nor finance connected with any hospital. It rents rooms, however, from the Royal City of Dublin Hospital, and in virtue of this tenancy the governors of the hospital have a small representation on the Council of the campaign.

PANEL PATIENTS IN LIVERPOOL.—At the annual meeting of the Liverpool Insurance Committee held in Liverpool on Dec. 9th, it was stated that the insured population of Liverpool numbered 327,000, as compared with 232,000 in 1912, an increase of 41 per cent. Last year nearly £134,000 was paid to doctors in the city, the average number on doctors' lists being 1085. Prescriptions numbered over 1,250,000, costing £45,000.

A COAT OF ARMS FOR THE LONDON HOSPITAL.—Mr. W. J. Paulin, the treasurer, has defrayed the cost of a grant of arms for the hospital, and at last week's quarterly court it was reported that the grant had just been made by Herald's College. One of the charges on the shield consists of three silver feathers with golden quills, in allusion to the inaugural meeting in 1740 at the Feathers Tavern in Cheapside. The original home of the hospital was a house in Featherstone-street.

SIR DAVID DRUMMOND'S PORTRAIT.—On Dec. 1st, at Newcastle, Sir David Drummond was presented with his portrait in oils to commemorate the jubilee of his connexion with the College of Medicine of the University of Durham. Mr. R. G. E. Mortimer, chairman of the governors, who made the presentation, traced his career since 1876, when he was first appointed to lecture in therapeutics. After Prof. Thomas Beattie and Sir Robert Bolam had paid personal tributes to his work and teaching, Sir David Drummond invited the College to accept the portrait which is to be hung among those of others who have devoted their lives to the College. Sir Thomas Oliver gratefully accepted this gift saying that it would find an honoured place in the building. It is the work of Mr. R. G. Eaves.

MEDICO-LEGAL SOCIETY: ANNUAL DINNER.—The annual dinner was held at the Holborn Restaurant on Dec. 9th, Sir William Willcox, the President, in the chair. Earl Russell proposed the toast of Medicine and Law, which he described as the two greatest dangers of modern civilisation, and Colonel C. T. Samman, Warden of the Society of Apothecaries, and Sir Leonard Kershaw, Registrar of the Court of Criminal Appeal, responded. Mr. Justice McCardie proposed the health of the Medico-Legal Society, which was, he said, in its twenty-sixth year, and in the full tide of successful achievement. It would be deplorable if in the future there was any feeling of antagonism between the law and medicine. Two questions might lead to such antagonism, the first being that of insanity. He did not believe in a law which was unprogressive; he did not think that the social and scientific philosophy of 1927 was the same as the social and scientific philosophy of 1843. But when insanity was discussed certain broad features were sometimes overlooked. Writers in the press, for instance, always seemed to treat insanity from the point of view of murder, but the principle touched questions of theft, forgery, assault, and other lesser offences. The second question at issue concerned medical security, and here again he begged for a broad view. The doctor cried "Health! health! Let us break down the legal obstacles which prevent it." But there was another standpoint. He himself would say: "Truth! truth! Open the shutters and let in the light of truth"; for the principle of truth was fundamental to criminal justice, and justice, as had been said, was the great interest of man upon earth. The test of this matter must be the test of utility—what was the greatest good of the greatest number. If this test was applied the problems were not so easy as they seemed, and it was of great importance to understand the outlook of the other side. The traditions of a profession were perhaps greater than any other traditions, and the Medico-Legal Society was engaged not only in the search for truth, but in strengthening bonds between two professions with the same ideals of public good and the same tradition of public service. The President, after speaking of the invaluable work done by his predecessor, Lord Justice Atkin, who for seven years had presided over the Society, spoke of the various ways in which its meetings were useful. When called upon to give evidence, he said, the doctor should strive not to be an advocate, but an honest witness. Medical witnesses often appeared biased because they could not say what they liked, but had to answer questions. Although the practice of forensic medicine was limited in England, the people in this country were at the heart of a great empire, and he would like to see a central institute in England for the teaching and investigation of this branch of science. The President concluded by speaking of the valuable services of Sir Walter Schröder, Mr. Ernest Goddard, Sir Bernard Spilsbury, and others who held office in the Society. Dr. F. G. Crookshank wittily proposed the health of the guests, to which responses were made by Sir John Anderson, Permanent Under Secretary to the Home Office, and Mr. Herbert Carson, President of the Medical Society of London.

DISEASES OF THE NERVOUS SYSTEM.—A course of lectures on this subject will be given at the National Hospital, Queen-square, London, W.C., from Jan. 30th to March 23rd. Other courses will also be available at the hospital, and particulars may be had from the Dean.

DONATIONS AND BEQUESTS.—Mr. John Wallace Taylor, of Sunderland, bequeathed a considerable sum of money to charity, including £500 each to the Sunderland Royal Infirmary and the National Children's Home and Orphanage, £250 each to the Sunderland Children's Hospital, the Sunderland Orphan Asylum, and Dr. Barnardo's Homes.—Mr. James Gould, of Parkhurst, Brighton, who left £83,202, directed that after payment of certain annuities the reserve of his property, amounting to about £30,000, be divided between five institutions, including the South Wimbledon Cottage Hospital, North Wimbledon Cottage Hospital, and the Royal Sussex County Hospital.—Mr. George Holloway, of The Prospect, Aylestone Hill, Hereford, left, among other bequests, on the death of his wife, £500 to the Hereford General Hospital, £500 to the Freemasons' Hospital, Fulham-road, £50 to the Hereford Eye Hospital, £50 to the Hereford Dispensary, and £50 to the Gwynne James Maternity Home.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Dec. 20th.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship. The Library will be open until 10 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, W.
MONDAY, Dec. 19th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Ward. 2 P.M., Dr. Trevor Davies: Gynæcological Department.
TUESDAY.—2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients.
WEDNESDAY.—10 A.M., Dr. Burnford: Medical Ward. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. MacDonald: Genito-urinary Department. 2 P.M., Mr. Bishop Harman: Eye Department.
FRIDAY.—10 A.M., Dr. Pritchard: Special Medical Treatment Clinic. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.
Medical and Surgical Out-patients, Operations, Special Departments, daily, 10 A.M. to 5 P.M., Saturday, 10 A.M. to 1 P.M.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
WEDNESDAY, Dec. 21st.—4 P.M., Dr. Richard W. Gilmour: The Certification of Mental Patients.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Dec. 19th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.S. £150.

Willesden General Hospital, Harlesden-road, N.W.—H.S. At rate of £100.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Hoylake (Cheshire) and at Cannock (Staffs.).

Births, Marriages, and Deaths.

MARRIAGES.

TAYLOR—CAREY TAYLOR.—On Dec. 8th, at Christ Church, Lancaster-gate, Arthur Reginald Lister, M.C., F.R.C.S., to Margaret Kathleen, eldest daughter of the Rev. and Mrs. Carey Taylor, of The Rectory, Winchelsea, Sussex.

TINCKER—BATES.—On Dec. 8th, at St. Mary's Church, Martlesham, Suffolk, Dr. R. W. Holden Tincker, of Painswick, Gloucester, to Kathleen Aldrich, eldest daughter of the late Rev. E. Bates, and of Mrs. Bates, of Martlesham Hall, Suffolk.

DEATHS.

JACKSON.—On Dec. 5th, in Paris, Marshall Jackson, W.A.M.S.

MARTIN.—At West Villa, Akenside-terrace, Jesmond, on the 8th inst., Ellen Renfree, wife of William Martin, M.D. Service at Jesmond Parish Church, Monday, Dec. 12th, at noon, and at Jesmond Old Cemetery immediately following.

—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

MEDICAL ASPECTS OF CONTRACEPTION.[1]

IN May, 1925, the National Council of Public Morals appointed a committee of 18 persons, for the most part doctors and divines, "to consider the ethical aspects of birth control from the view of Christian people." This committee drew up a report,[2] the main conclusions of which may with advantage be here set out.

The 1925 Mixed Committee's Conclusions.

1. "That for the Christian, spiritual reinforcements are available, where ordinary moral resources are insufficient; that such spiritual help can be relied upon by those united in Christian wedlock; and that the family is a Divine institution."

2. "The ideal method of birth control is self-control." "By this term we mean the complete abstinence from intercourse throughout those periods of marriage when, for one reason or another, conception is not desired." Referring to those who desire to keep their families within "workable limits," the report says of self-control: "Its feasibility in such cases—probably indeed in all cases—is, we believe, gravely underrated."

3. "The deliberate disconnexion by mechanical means of sexual satisfaction and its natural result opens the door to grave social perils, and a serious responsibility therefore lies upon the conscience of married people who adopt this practice." The grave "social evils" arise from the fact that "there is a close connexion which cannot be ignored between the problem of conception control and the problem raised by sexual promiscuity."

4. "Normally each couple should look forward to a family of four or five children at the least."

5. "The comparatively modern practice of conception control, and in particular the artificial methods used, call for a much fuller investigation than they have hitherto received from the medical, economic, and social point of view."

From the above conclusions it will be seen that the National Council of Public Morals is a body of a kind that is not disposed lightly to advocate birth control.

Shortly after the publication of the above report a medical committee was appointed by the National Council of Public Morals to report on the medical aspects of birth control. This book is that report. The medical committee consisted of 14 persons, of whom six had previously sat upon the committee which reported on the ethics of birth control. These were: Sir Arthur Newsholme and Mr. Charles Gibbs, Dr. C. J. Bond, Dr. A. K. Chalmers, Dr. Agnes Dunnet, and Dr. Letitia Fairfield. But Dr. Fairfield—who had signed a reservation to the ethical report to the effect that "We believe that the use of contraceptives is a frustration of God's design in nature and of the marital act, and as such is unjustifiable"—was unfortunately compelled to resign from the committee after six meetings owing to pressure of professional work.

Unlike certain other recent publications that have purported to expound medical views on contraception, this report contains much relevant and valuable evidence. In fact it is indisputably the most authoritative pronouncement upon the subject that has yet appeared. The committee has been at pains to collect statements and evidence from witnesses connected with four birth control centres with records of over 12,000 cases, from two American doctors who reported on the birth control movement in America and on the continent, and from Prof. F. A. Marshall, Mr. T. A. Webster, Lord Dawson of Penn, and Dr. Killick Millard, Dr. R. A. Gibbons, Dr. Binnie Dunlop, and Dr. Crichton Miller. The committee's conclusions are embodied in a report of 14 pages, which constitutes the first part of the book. The second and much longer part consists of the various statements and evidence submitted to the committee. We indicate here the chief medical conclusions which have been reached by the committee.

The Medical Committee's Conclusions.

1. "In the close relationship of married life, the effects of continued abstinence may be grave for persons of certain temperaments. Abstinence, while it is the obvious, and, from the ethical point of view, the ideal procedure, when it is desired that no children should be born, is impracticable for the majority of young married people."

The divergence of view as to the practicability of abstinence between this statement and that embodied in the ethical report illustrates the difference between the

[1] Medical Aspects of Contraception. By a medical committee. London: Martin Hopkinson and Co., Ltd. 1927. Pp. 183. 10s. 6d.

[2] The Ethics of Birth Control. Macmillan and Co., Ltd. 1925.

theological and the medical approach to the question of abstinence.

2. "Coitus interruptus is practised by a very large number. The principal objection is that incomplete gratification sometimes produces well-authenticated psychological illnesses in both participants, as well as pain, tenderness, irritability of temper, hysteria, and impotence."

3. "There is strictly no safe period, as conception may occur at any stage of the menstrual cycle. Experience shows, however, that there is a time in which the chances of conception are materially diminished—namely, from about the eighteenth day after the first day of the preceding period to the end of the cycle." It is to be noted that this view seriously conflicts with that of the ethical committee which expressed itself to the effect that: ". . . there is a large body of evidence that, as an alternative to complete abstinence over long periods, strict limitation of sexual relations to *four or five days* in the middle of the intermenstrual period, does diminish the risk of pregnancy." The large body of evidence was not specified. But whatever it was, it militates in the most unequivocal manner with the evidence presented to this committee by Prof. Marshall.

This evidence is based on the assumption that the human ovum and spermatozoon remain capable of fertilisation for similar lengths of time to those of the rabbit—namely, 4 and 30 hours respectively after discharge—and upon evidence that the usual moment for ovulation in the woman is from the fourteenth to the seventeenth day after the beginning of the menstrual discharge. This evidence, which is forthcoming from the observations of Dr. Wilfred Shaw, is of very great importance since, if true, it follows that the mid-menstrual period is the one in which the chances of fertilisation are incomparably greatest. Far from being a "safe" period, as taught by the Roman Catholic Church,[3] the mid-menstrual period would, par excellence, be the unsafe period.

4. In the opinion of the committee the best contraceptive method for women free from genital disease is a combination of a rubber occlusive diaphragm and a spermicide in a non-fatty vehicle which should be applied above and below the diaphragm. But to this view the important reservation is made that "it requires a medical practitioner to fit the appropriate size and to teach the woman to place it in position herself."

5. With regard to the effects of contraception on individual health, the report says: "With regard to the woman, evidence brought before us suggests that in cases in which, on medical grounds or on account of already large families, contraceptives are advisable, their use brings about an improvement in general health owing to freedom from anxiety as to the possibility of pregnancy, increased happiness in the home, better outlook, and greater affection for the children."

6. Referring to how women can best be given advice on contraception, it is stated that: "Hospitals should be centres for advice and instruction on the subject. When a hospital has an obstetric and gynæcological department, this would be the most suitable place."

7. "The amount of scientific information as to the efficiency of contraceptives based on statistical data is very small. On this subject exact information could only be based on the collection of scientific data extending over a period of years."

This report should be read by all interested in the subject. It can safely be recommended as the best-grounded presentation of the medical aspects of birth control that has yet been made.

Those who are anxious to assist this committee in the process of investigation which it feels to be so necessary, can best do so by collaborating with a Birth Control Investigations Committee, the aims of which were explained in a letter from Sir Humphry Rolleston which appeared in our issue of Oct. 29th. The secretary of this committee is the Hon. Mrs. Marjorie Farrer, 41B, Clanricarde-gardens, London, W. 2, who will welcome communications from members of the medical profession.

[3] "When all other deterrents fail, it is lawful, according to the teaching of the Church, for married people to limit intercourse to the mid-menstrual period, when, although conception may occur, it is less likely to occur than at other times" (Birth Control. By Halliday Sutherland. Harding and Co. P. 153).

MARSHALL'S LYSOL.

THIS preparation is manufactured by Lysol, Ltd., Raynes Park, S.W. 20, to the original formula of Schulke and Mayr, A.G., Hamburg, and is now to be known by the registered trade mark "Marshol." Medical men are asked to specify Marshol on their prescriptions instead of just Lysol. Schulke and Mayr, A.G., Hamburg, is an associated company of Lysol, Ltd., and Marshol will continue to identify the original Lysol well known for over 30 years.

A SPANISH MEDICAL DIRECTORY.

THERE are many signs of a revival of scientific medicin in Spain. We have lately received a large volume of 143 pages entitled "Anuario Médico de España," publishe with distinguished collaboration under the editorship o Señor Federico Bonet, pharmacist, in Madrid (Av. Cond Peñalver, 21 y 23). This is the first issue of a new director containing lists of medical men, dentists, veterinary surgeons chemists, colleges, faculties and schools, hospitals, clinics sanatoriums, laboratories, a summary of Spanish legislatio concerning medicine, and notes on medical history. Particu larly interesting is a long alphabetical list of pharmaceutica proprietary specialties registered in Spain, with the date an number of the registration, and sometimes with the name slightly altered and unfamiliar. It is inevitable that ther should be a few errors in a new work of this magnitude, bu the undertaking deserves every praise as it will serve most useful purpose in Spain and throughout the worl generally.

DIPLOMAS IN MEDICAL RADIOLOGY AND ELECTROLOGY.

IN our recent Students' Guide no mention appeared the Diploma in Medical Radiology and Electrology grante by the University of Liverpool. Candidates before admissio to the examination for this diploma must possess a registrab qualification, approved by the University in medicine an surgery, and must have attended courses of instruction i (*a*) physics (two terms), (*b*) (i) radiology, and (ii) electrolog during six months in the X ray and electrotherapeut departments of a hospital or hospitals. An examination held in March each year, the subjects being (*a*) physic (*b*) radiology and electrology. Examination in either pa may be taken separately. Fees: tuition, £24 5*s*; examin tion and diploma, £6 5*s*. These courses commence durir the first week in October. Application should be made t the Dean, Faculty of Medicine, the University of Liverpoo

SCOTT'S PATENT MALT CHARCOAL BISCUITS.

WE have received from Messrs. R. M. Scott, of Ipswic manufacturers of wholemeal biscuits, a sample of the Malt Charcoal Biscuits which, in flavour, resemble a reaso ably sweet biscuit, while there is an entire absence of gritt ness. The biscuits should prove useful in gastric conditio where indicated; they are conveniently packed in t boxes, thus conserving their natural crispness. They a intended to be eaten after meals.

A QUESTION OF SUPERANNUATION.

Dr. J. T. Macnamara, medical officer and vaccinator the Ladywell Institution, Lewisham, has addressed a lett to the Ministry of Health asking for a public inquiry in the administration of all the institutions controlled by t Bermondsey Board of Guardians. He bases his deman upon a contention that his own office has been constitut legally as an appointment for life, so that any resolutio determining the appointments of all over 65 years of a are illegal as far as he is concerned. In particular referen to his own institution, he points out that a surprise vi from a representative of the Ministry of Health reveal a very satisfactory state of affairs, and he submits that t replacing of a whole-time medical officer will be uneconomic and not in the interests of the public service, referrin presumably, to what he believes to be an intention of Board.

SPLENDID ISOLATION.

To the Editor of THE LANCET.

SIR,—There are two country practices which are almo accurately separated by a main road for two miles of length, each doctor living four miles from the bounda These two practices have been worked side by side, under t same board of guardians, by the same two men, for ov 30 years, and last year each of them told me that, far as he knew, he had never seen the other. Is this record? I am, Sir, yours faithfully,

Clevedon, Dec. 9th, 1927. R. L. WASON.

"MULTIWIDTH" PLASTER.

IN order to overcome the inconvenience of carryi several spools of adhesive plaster in a medical equipme case, and the trouble of cutting a wide strip into narr widths, Messrs. Fassett and Johnson, Ltd., of 86, Clerkenwe road, London, E.C., have devised a single spool measuri 3 in. in width which carries Mead's rubber adhesive plast or Seabury's oxide of zinc plaster cut into widths of ½, ¾, and 1½ in. Any of these widths can be rolled off the sp as required without disturbing the others. Each sp contains 5 yards, so that the total area of plaster contain on a spool is 3 in. by 5 yd. The saving of space as well convenience of handling are features of this new plast packing.

A Discourse

ON

EHRLICH'S "CHEMOTHERAPY,"

AND ON CERTAIN GENERAL PRINCIPLES WHICH REQUIRE TO BE BROUGHT INTO APPLICATION IN ALL TREATMENT OF BACTERIAL DISEASE.

BY SIR ALMROTH E. WRIGHT, M.D., D.Sc. DUB., F.R.S.,

PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON; PRINCIPAL OF THE INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL.

EHRLICH, who was the originator of the therapeutic ethod which is to supply a principal theme of this iscourse, elected to call this method of his devising—iemotherapy. That appellation must be judged nfortunate. For it runs counter to all principles f sound nomenclature to transfer to a species an ppellation which properly belongs to a genus (and ie name chemotherapy belongs, of course, by right,) every form of chemical treatment). A delinquency nomenclature such as this can be retrieved only y adding to the appellation given a full complement defining and interpreting clauses.

Here the following complement of glosses must e supplied :—

1. Chemotherapy, in Ehrlich's sense, signifies aggressve chemical action exerted on a biological element hich is parasitic upon the organism. In other words, iemotherapy, in Ehrlich's sense, means for all rdinary purposes: *specific parasitocidal chemoerapy.*

2. Further, chemotherapy, as understood by Ehrlich, gnifies chemical action, which, while attacking rasitic elements, leaves the organism fundamentally iaffected. (In other words, chemotherapy, in rlich's sense, would, expressed in his terminology, : *specific parasitocidal, predominantly monotropic emotherapy*).

3. Lastly, the chemotherapy Ehrlich had in view is treatment by artificially manufactured chemical oducts, as distinguished from products elaborated the animal organism in response to infection or ccination. In conformity with this, Ehrlich's emotherapy would be properly described as: *ecific parasitocidal, predominantly monotropic armacotherapy.* Let me, in the sequel, use the m *pharmacotherapy* where Ehrlich would have oken of *chemotherapy.*

We may now turn from the definition of the method the conceptions which gave it birth. The fundaental principle of pharmacotherapy is that expressed Ehrlich's dictum: that every substance which erts any chemical action upon a body cell or tissue, parasitic organism, does so by virtue of its anchor- itself—i.e., by laying chemical hold upon the ment in question. That is the doctrine incorated in Ehrlich's formula: *corpora non agunt nisi ita.* The accessory ideas which afterwards grouped mselves round this foundational axiom were pounded by their author through the vehicle of hnical terms. In choosing technical terms as the icle for his ideas, Ehrlich was, as reflection will w us, acting under happy inspiration. Let us, this connexion, note that it has been pregnantly l of words in general—and this holds in a very cial sense of technical terms—that they are in lity "agents of universal instruction." Further, rds of all kinds, and "terms of art" more than furnish a *memoria technica*—one which keeps nind things that would, if the words were not there retain them, escape from the memory. The in apophthegm recounts it well: *Nomina si cis, perit et cognitio rerum.*

n view of what has just been said, it will be seen t we may fittingly begin by studying the vocabulary which Ehrlich has given expression to his conceptions on pharmacotherapy. In setting out that terminology it will be convenient to place in each case, the one over against the other, those terms that are antonyms, and to print in italics such words that are either lacking in precision or would be prone to carry into the mind erroneous implications.

EHRLICH'S APPARATUS OF TECHNICAL TERMS.

Receptor.	Haptophore (Hapten).
Mono-tropic.	Poly-tropic.
Organo-tropic.	*Parasito-tropic.*
(For example: neuro- hæmato- leucocyto- and erythrocyto-tropic.)	(For example: bacterio- staphylo- pneumo- or trypanosomato- tropic.)
Dosis Tolerata.	*Dosis Efficax.*
Therapia magna sterilisans.	*Therapia sterilisans fractionata.*

Cribrum therapeuticum.

We may now, though this will involve rehearsing some very familiar material, proceed to pass in review this syllabus of technical terms. The expression *receptor*, as employed by Ehrlich, designates the atomic group in the body cell, tissue, or parasitic organism upon which the chemical agent in question anchors itself. The expression *haptophore* (which is the antonym to receptor) denotes the atomic group by which the chemical agent in question anchors itself to (the Greek says *grasps*) the receptor. The suffix *-tropic* applied to a chemical agent indicates that the substance in question combines with (the Greek says *turns toward*) the kind of cell, tissue, or parasite which is designated by the verbal stem to which the suffix is articulated. The classification into *parasito-* and *organo-* (or as we might better say instead of organo-, *histo-*) tropic is prone to mislead, inasmuch as it might erroneously suggest to the mind that the chemical affinities here in question are mutually exclusive, and that a chemical agent which is *parasito-tropic* cannot at one and the same time be *organo-tropic.* This particular blemish may, however, be deemed retrieved by Ehrlich having taken up into his vocabulary the expressions *mono-* and *poly-tropic* (these were coined by me in the mould supplied by Ehrlich), which definitely enunciate that an agent may combine either exclusively with one kind of cell, tissue, or parasitic organism, or, as the case may be, with a number of different kinds of cell, tissue, parasitic organisms, or any combination of these. But what we really require to know about a *polytropic* drug (and practically all drugs are *polytropic*) is whether it combines preferentially with, let us say, the parasitic element, and, *faute de mieux*, with the tissues and cells of the host; or, vice versa, preferentially with the cells and tissues of the body and only *faute de mieux* with the parasite. This might perhaps be conveniently expressed by saying that what we want to know of a drug is whether it is *proterotropic* for the parasite and *hysterotropic* for cells and tissues of the body, or whether it is *proterotropic* for the host and *hysterotropic* for the parasitic organism.

Following on now in our table we come to the expressions *dosis tolerata* and *dosis efficax.* Upon the accurate determination of these a very great deal depends. For the doctrine of Ehrlich tells us that the value of a therapeutic agent depends upon the *dosis tolerata* being definitely larger than the *dosis efficax.* And that doctrine is clearly empty of content if in this therapeutic fractional coefficient $\left(\frac{dosis\ tolerata}{dosis\ efficax}\right)$ the terms which serve as numerator and denominator, are ambiguous. And *de facto* that is the position of things. That the term a *dosis tolerata* is a term of ambiguous meaning will be obvious when we consider that a *dosis tolerata* might mean on the one hand a dose which is *tolerated by the organism taken as a whole*, and on the other hand a dose which is *tolerated by the leucocytes.* Ehrlich, when he used the term, had in view, of course, the dose *tolerated by the body as a whole.* Further, he had in view not the, presumably smaller, quantum that can be adminis-

tered to the diseased, but that, presumably larger, quantum which can be given to healthy men or animals without killing or manifestly poisoning them. But a clinically tolerated dose as thus defined is in point of fact in many cases a dose which weakens or abolishes the antibacterial defence of the body by poisoning the leucocytes. Such a quantum is obviously quite improperly designated a *dosis tolerata*. It would be much better called either a *dosis inermans* (i.e., a disarming dose) or a *dosis destituens* (a dose which leaves the body destitute of leucocytic defence).

The practical importance of the distinction between that (generally larger) quantum of a chemical agent which can be clinically tolerated and that (generally smaller) quantum which can be tolerated by the leucocytes is of obvious practical significance. It is common sense that a quantum of a chemical agent which paralyses the leucocytic defence must when administered to an animal organism which is suffering from a bacterial infection or which is (I am thinking here of prophylactic inoculation) to be exposed to risk of such infection, must work for mischief.

We turn now to the consideration of the term *dosis efficax*. A moment's consideration will show that this expression also is ambiguous. It may mean, to begin with, either a *dosis omnimo sterilisans* (such a dose as would sterilise the entire body), or (and this would be the ordinary meaning of the term) a *dosis sanguini-sterilisans* (a quantum that would sterilise the blood). And again the term *dosis efficax* might mean a *dosis uno ictu efficax*, or a *dosis sæpius repetenda*. Or, finally, it might mean the grand total dose of the drug which is, given in divided doses, required for the achievement of a satisfactory result.

This brings us to the consideration of Ehrlich's therapeutic projects. The first of these, the *therapia magna sterilisans*—i.e., the project of sterilising the whole body by a *dosis uno icto efficax*—that is sterilising it once and for all by a single dose of a drug—was definitely relinquished by Ehrlich in the salvarsan treatment of syphilis, when practical experience of this disease had brought it home to him that the largest dose of his arsenical remedies which could be exhibited without fatal consequences, failed to extirpate syphilitic infection.

Coming now to the *therapia sterilisans fractionata*, let us note with respect to the attribute *fractionata*, that this quite fallaciously suggests to the mind that the therapeutic procedure here in question proceeds upon the same lines as the procedure of fractional sterilisation employed in bacteriological laboratories in the preparation of culture media which do not support high temperatures. The fractional sterilisation which comes in that case into application depends upon the principle that microbic spores, which an application of moderate heat fails to kill, grow out when that heat is withdrawn into forms susceptible of being killed by such moderate temperatures as were initially ineffective.

Now, nothing of the sort can be supposed to supervene in the case of syphilitic spirochætes or other microbes living parasitically in the body. Not only are these micro-organisms not converted during treatment into more vulnerable forms, but, as Ehrlich's own work and that of Morgenroth showed, parasitic microbes tend to become more resistant to whatever drug is administered.

By the establishment of this general law, Ehrlich, in point of fact, withdraws from his *therapia sterilisans fractionata* all that scientific countenance which his nomenclature had illegitimately procured for it. And we shall presently have to inquire whether there is, in point of fact, any other scientific defence that can be adduced in defence of this seemingly unwarranted therapeutic procedure.

Finally, a few words may be said about the therapeutic procedure which employs two pharmaco-chemical agents and attacks the original microbic population with the first, and then such residue of that population as may survive with the second agent. This therapeutic device was called by Ehrlich a *cribrum therapeuticum*, for it was, as seen in his mind's eye, a device in which the physician places in positio in the blood first a chemical barrier or grid so oriente as to intercept the bulk of the infecting microbes and after that a second chemical grid oriented s as to hold back any micro-organisms which migh succeed in getting past the first filter trap. As soo as we visualise this method of attack and meditat upon it, our mind sees that it can affect only microbe in the blood stream and the regions irrigated by thi and that it will leave quite unscathed those tha have already penetrated into the remote backwaters

With this we have completed our critical stud of Ehrlich's terminology, and there will have bee carried away from that critical analysis at least thi that the doctrine enunciated in those terms i inadequate and also in many respects erroneous Out first task must accordingly be to try to win ou way to a fuller and clearer comprehension of th problem which confronts the pharmacotherapist.

Reflection will show that we have here (and th same, of course, holds of immuno-therapy) not on but two separate problems. The one is a purel chemical problem; the other a problem in therapeuti engineering.

Let us consider, first, the one which is exclusivel chemical. The task of composing a pharmaco chemical bactericidal agent which shall be intra corporeally active is, as will be appreciated, infinitel more difficult than that of producing or finding a antiseptic of the ordinary kind. When a chemis is asked to provide the ordinary kind of antiseptic all he is asked to do is to find a chemical agent whic will destroy microbes, it being understood that th microbes shall be lying nude and exposed to chemica attack. When, on the other hand, a chemist is aske to produce a pharmaco-chemical bacterial agen which shall be intracorporeally active, there is require from him an agent which will kill this or that specie not only when it is lying nude, but also when it i enveloped in albuminous fluids and secretory fluid of all kinds. And there is further required of hin that he shall compose an agent which will ki microbes in the body without injuring physiologica elements which are either directly essential to lif or requisite for antimicrobic defence.

And the above does not constitute by any means full account of what is required of a pharmaco-chemica agent. Not only must such an agent be poisonou for microbes, and so far as possible non-poisonou for the organism, but it must also be rapid in actio so that it may complete its task before it is eliminate or rendered inactive.

The importance of this provision will be clear whe we consider that it has been ascertained with respec to optochin,[1] operating upon the pneumococcus i blood in vitro in the maximum dose admissible i treatment, and again with respect to neosalvarsan, operating upon the streptococcus under the sam conditions, that these drugs do not poison th microbes until they have been in action for a perio of many hours. And in this connexion there must b taken into account also the fact that in the bod pharmacotherapeutic agents are subject to rapi wastage. We know, to begin with, that the kidne and liver are continuously at work removing foreig elements from the blood, and we know, further with respect to bactericidal drugs, that unless the have been completely purged of their affinity fo albuminous substances, they are, when employed i the body, subject to a further important wastage b the fact that they tie themselves up to the albuminou elements of the blood and tissues.

Having realised how difficult it is for the chemis to produce (and, of course, we cannot reasonably expect nature to provide ready-made) effectiv pharmaco-chemical bactericidal agents, we may no turn to consider the further problem which confront the physician who has to bring such agents int application, not only (for that is a comparatively

[1] Moore and Chesney: Archives of Internal Medicine, 1917 xxi., 659.

[2] Colebrook, L.: Unpublished researches.

simple matter) upon microbes circulating in the blood, but also (and this is what is really difficult) upon microbes dispersed throughout the organism.

It is, in point of fact, a grave blot upon Ehrlich's wonderful work upon pharmacotherapy that he failed to realise why his projected *therapia magna sterilisans* in syphilis had come to nought. He, as we saw above, attributed this to his arsenical preparations having still, after all his efforts, retained considerable toxicity. Consideration of his now universally familiar therapeutic fractional coefficient $\left(\frac{dosis\ tolerata}{dosis\ efficax}\right)$ does not, however, elucidate the failure of the *therapia magna sterilisans*. For that formula quite fails to explain why a drug which is efficacious when applied to one part of an infecting microbic population, is ineffective with respect to another part of that same population.

Now, as will be shown, the real answer to this is that one part of the infective microbes are circulating in the blood or lie in regions to which there is ready access from the blood, while the other part lies in regions so physiologically remote that it might quite safely be postulated in connexion with treatment by arsenic, that even were 1000 times a lethal dose to be administered, no trace of that agent would ever penetrate there.

It will help us to realise that this is the true position of affairs if we consider for a moment the plan upon which the organism is constructed. The body is, in point of fact, constructed upon a plan of water-tight or almost water-tight compartments. Between the blood and the lymph is interposed the capillary endothelium which prevents all direct inter-penetration of fluids and permits only of interfusion by dialysis and restricted filtration. The lymph again is divided from what we may call the *secretory fluids* by secretory membranes. How rigidly such membranes divide off the mother liquor (the lymph) from the secretory product is seen when we contrast the composition of the lymph with that of (*a*) the cerebro-spinal fluid; (*b*) the synovial fluid of the joints, bursæ, and tendons; (*c*) the aqueous and vitreous humour; (*d*) the mucus which coats the surfaces of the mucous membranes; and (*e*) the secretions proper, such as the tears, the saliva, the milk, the bile, and the urine.

It will be manifest from the above that the fluids of the body can, from the point of view of their accessibility to therapeutic operations, be ranged under three categories. There is, to begin with, the blood which can be directly influenced by the injection of chemical agents; then the lymph which can normally (wounds are here excluded from consideration) be reached only indirectly through the medium of the blood; and, finally, the secretory fluids which can be reached only remotely through the medium of the lymph.

Before addressing ourselves to the problem as to how chemical agents (I use the comprehensive term because the problem we are engaged upon concerns immuno-chemical as well as pharmaco-chemical agents) can be brought into operation not only in the blood, but all over the body, we must seek to arrive at a clear conception as to what will happen when microbes obtain access, as the case may be, to the blood, the lymph, or the secretory fluids. And we shall do well to put to ourselves, in connexion with each category of fluid, the following three questions: *first:* Are microbes killed in this fluid by an onslaught of first intention? *Secondly:* Do such survivors as are left over after such onslaught make good their footing in the medium which has proved fatal to the majority? and *lastly:* How can such ensconced microbes subsequently combated?

We may begin by considering what happens when microbes obtain access to the blood stream. Here, except in the case where specially virulent microbes are in question, all, or at any rate a large proportion, are killed off by an onslaught of first intention, the sero-vulnerable microbes being destroyed by the torrent of bactericidal blood fluid which is brought to bear upon them, while the serophytic microbes (those which can draw nutriment from, and can accordingly grow out in the blood fluids) are, as soon as they get stranded in capillaries, phagocytosed and killed by the leucocytes. Further, when they are carried into the liver they are killed there after ingestion by endothelial cells.[3]

The microbes which survive this first onslaught make good their footing by rendering the blood apophylactic. They effect this (*a*) by absorbing agglutinating, opsonic, and bactericidal elements from the blood fluids, (*b*) by secreting toxins which either keep the leucocytes at bay or kill them.

Where there has been an incursion of large numbers of living microbes into the blood, and likewise where a massive dose of vaccine has been administered, the whole circulating blood may be brought down to a lower level of antibacterial, or, to speak in chemical terms, bacteriotropic potency—in other words, a general *negative phase* may be induced.

More frequently, however, the antibacterial potency of the blood will be reduced only in the immediate environment of the surviving microbes. These will, as a result of this, be lodged in non-bacteriotropic, or, as we may also call them, ecphylactic niduses. The formation of ecphylactic foci in infected tissues and organs will, as reflection will show, be dependent upon an arrest of the blood stream. So long as the circulation is maintained, the blood which has, by passing through the infected region, lost in anti-bacterial power will be continuously replaced by newly arriving antibacterially potent blood. When, however, the circulation is anywhere arrested, the blood will, by continued contact with the bacteria, become more and more poisoned and depleted in protective substances. And, *mutatis mutandis*, this will apply also when a portion of infected blood becomes converted into a clot, or when a quantum of non-coagulated blood is brought to a standstill by the blocking of a vessel by clot.

But intravascular clotting is very far from being the only event that will produce a local arrest of the circulation. Other physiological happenings can also bring about that result. We now know from Krogh's researches [4] that capillary loops are intermittently shut down by muscle cells upon their walls, and again opened up. And when we reflect on what must happen when capillaries through which infected blood is passing are shut down, we realise that the microbes which are in passage may be left high and dry upon the vessel walls or be imprisoned in isolated parcels of blood left behind in the lumen of the vessels. Opportunity may in this way be provided for the elaboration of ecphylactic foci. In relation to this I have proffered by way of suggestion that typhoid spots and other bacterial skin eruptions may quite well originate in this manner. It should be borne in mind in connexion with this suggestion that comparative measurements of (*a*) the agglutinins of serum derived from lymph admixed with blood obtained by pricking typhoid spots, and (*b*) of the agglutinins of blood obtained from the finger of the typhoid patients in question, have brought out the fact that the blood fluids obtained from the bacterial rash have only a tithe of the agglutinating power of the circulating blood.[5] And, presumably, exactly the same holds of the bactericidal power of these fluids. Further, in connexion with the development of bacterial rashes in typhoid fever and certain other septicæmias, this additional point may be considered. Microbes stranded in empty capillary loops in the dermis will probably, inasmuch as such microbes are less likely to be disturbed by a flushing out of the capillaries, find more favourable conditions for growth than would microbes stranded in capillary loops in muscles and glands. For, supposing microbes to be held back in the situations last mentioned by the closing down of capillaries, they would, when the

[3] Manwaring and Coe: Jour. of Immunology, 1916, i., 401. Opie: General Review, Jour. Amer. Med. Assoc., Nov. 14th, 1925.
[4] Harvey Lectures, Series XVIII., 1922–23.
[5] Wright and Lamb: THE LANCET, Dec. 23rd, 1899.

hyperæmia which goes with muscular and glandular activity supervenes, inevitably be swept out to meet their fate in the general circulation.

In addition to the machinery which closes down the capillaries there is in the organism other machinery which brings to a standstill blood previously in circulation. It has recently been shown by Barcroft [6] that the spleen regulates the volume of blood in circulation by loading itself up with additional blood when the volume of the circulating fluid is in excess of requirements; and by disbursing that blood when a larger volume of circulating fluid is required. It needs no gift of second sight to see that the withdrawal of blood into the stagnant diverticulum of the spleen will, in the case where that blood is infected, provide the microbes with opportunity for encasing themselves in ecphylactic envelopes. This no doubt accounts for the infecting microbe being regularly found in the spleen in typhoid fever, in Malta fever, in spirillum fever, and in anthrax; and for its being found there in large numbers (and in typhoid fever in the form of definite colonies) when the circulating blood is sterile. And again in this connexion it deserves to be remembered that in the three first-mentioned septicæmias with regard to which data are available [7] the blood from the spleen has been found in each case conspicuously inferior in antibacterial potency to the blood from the heart.

Turning now to the question as to how microbes which have ensconced themselves in ecphylactic niduses in the blood are subsequently combated, we may note that here both mechanical factors (in the form of alterations in the circulation), and chemical and biological factors (in the form of increased antibacterial potency of the leucocytes and blood fluids) may play their part. It will suffice in connexion with these last to note that the leucocytes which may under the stimulus of infection have acquired increased confrontation power and phagocytic efficiency; and the blood fluids, which may under that impulse have acquired increased bacteriotropic and antitryptic powers, may by degrees come into operation upon the microbes sheltering in ecphylactic niduses. With regard to the mechanical factors, the points of importance are these: Blood-vessels which have been closed down may be opened up, the circulating blood with its superior antibacterial potency being this let in upon bacterial colonies which have grown out in ecphylactic niduses. Further, by contractions of the spleen blood which has been lying stagnant in its diverticula may be returned to the circulation, the contained bacteria being thus resubjected to attack by the circulating blood fluids and leucocytes.

It is in this connexion interesting to ponder the question as to why in the ordinary streptococcal septicæmia there is neither growth of streptococci in colonies in the spleen, nor a bacterial eruption such as would indicate an outgrowth of microbes in the capillaries of the skin. In connexion with that problem it may be thrown out by way of suggestion that the absence of streptococcal growth in the spleen and in the cutaneous capillaries may perhaps stand in relation to the rigors. For see-saw changes in the circulatory system are of the essence of a rigor. In the cold stage the capillaries of the skin would be closed down, room being found for the expelled blood by the opening up of the diverticula in the spleen. In the hot stage the capillaries of the skin would be widely thrown open and any microbes which had been stranded there would be carried off into the circulating blood. And concurrently the spleen would contract to furnish the additional volume of blood required, and with this any microbes which had found temporary lodgment in its diverticula would in their turn be swept out into the blood stream.

We can now pass from the events which follow the introduction of microbes into the circulating blood to those that ensue when microbes are implanted into the lymph-infiltrated tissues. With respect to these two points require to be borne in mind: first, that there is not normally to be found there any population of leucocytes such as could protect them against an incursion of microbes; and, secondly, that lymph which lies in the tissues would, if we may generalise from such data as are available, appear to be of less bacteriotropic, and in particular of less antitryptic, potency than the circulating blood fluids. Microbes entering the tissues will accordingly be subjected to no such immediate assault as microbes entering the blood. Nevertheless, if we look a little further and regard the fact that reinforcements of leucocytes and serous fluid can be very rapidly poured in from the blood we may (and in reality this is merely forsaking verbal accuracy for substantial truth) accredit the lymph lying in the tissues with a faculty of killing microbes by first intention.

But—and this is all important as explaining the conditions under which microbes establish themselves in the tissues—effective killing of microbes in the lymph spaces is achieved only when there is adequate transport of phylactic elements from the blood into the tissues, and further only when a proper balance is conserved between its two elements, leucocytic immigration and serous effusion.

(1) When leucocytic immigration into the focus of infection is inhibited by the agency of bacterial toxin, and serous fluid containing few or no leucocytes is transported into the seat of infection, there is furnished to the invading microbes (let it be remembered that these are in practically every case serophytes) a ready-made ecphylactic nidus. To begin with, the transuded fluid provides the microbes with a favourable nutrient medium. Added to that phagocytic activity on the part of such leucocytes as are contained in the effusion is rendered impossible by the fact that leucocytes cannot dive into fluid and swim out in pursuit of microbes. And, finally, such leucocytes as have come out into the lymph cannot by reason of their paucity communicate to it any appreciable bactericidal power. This will be the position of affairs when we are dealing with œdematous swelling of the subcutaneous tissues or effusion into serous cavities.

(2) The formation of ecphylactic niduses in infected tissues will perhaps be favoured also in the case where emigration preponderates over transudation, and the emigrated leucocytes collect forming impacted foci of suppuration. In foci—such as we have in abscess sacs and in suppurating wound cavities—the leucocytes will under the influence of bacterial toxins, of deleterious external influences, or of both, first lose their power of phagocytosis and then succumb and disintegrate. When that happens the trypsin set free will reduce the antitryptic power of the surrounding fluid; and given that a considerable number of leucocytes disintegrate in a relatively small quantum of liquor puris, this will be converted into a definitely tryptic fluid. In the former case serophytic growth will be facilitated, and in the second not only serophytic but also non-serophytic microbes will be lying in a medium in which they can pullulate unrestrained.

Passing now from the study of the genesis of ecphylactic foci in the tissues to inquiry as to how the organism can combat microbes which are growing in such a nidus, there have here, as in the case of the blood considered above, to be regarded, first mechanical and secondly chemical and immunological factors. In the case where an immoderate serous effusion has converted the site of infection into an ecphylactic nidus, the position (we are assuming, of course, that there is no therapeutic interference) can be retrieved by a spontaneous resorption of the excess of fluid and a supplementary emigration of leucocytes. Similarly where a breaking down of emigrated leucocytes and a corresponding blunting off of the antitryptic reaction of the transudation fluid has converted the site of infection into an ecphylactic focus the situation would be retrieved by the supervention of further

[6] THE LANCET, 1926, i., 544.

[7] **Courmont**: Comptes Rendus Soc. de Biologie, 1897. **Wright and Lamb**: loc. cit.; **Lamb**: Scientific Memoirs by Medical Officers of the Army in India, Part XII., 1901.

serous effusion. For such superadded effusion would counteract leucocytic disintegration and at the same time limit serophytic, and arrest if such were in question serosaprophytic, microbic growth. Finally, it requires to be added by way of a rider that if the reinforcing leucocytes which immigrate into the focus of infection possess by virtue of an immunising response made by the organism increased confrontation power and increased phagocytic efficiency, and, similarly, if the reinforcing transudation fluid which is effused into the focus of infection has greater antibacterial potency, this improvement in the quality of the reinforcements will in each case conduce to a greater slaughter of microbes.

Having now considered how bacterial infections are combated in the blood, and in the lymph and tissues which are impregnated with lymph, our next task will be to inquire what provision exists for dealing with microbes which have found their way into a secretory fluid, or a tissue which is impregnated by or irrigated with a secretory fluid. In this inquiry a distinction must be made between three categories of secretory fluids. The first kind would be those which have the function of irrigating internal or external surfaces which lie open to infection from without. The secretory fluids which would be comprised in this class—in other words, tears, saliva, and mucus—possess the power of destroying all, other than specially acclimatised species of microbes. Let it be noted in passing that the bactericidal and bacteriolytic power here in question is a function of an antibacterial element (the so-called lysozyme)[8] which is distinguishable from the antibacterial elements of the blood fluids. The second class of secretory fluids comprises the synovia of the joints, tendon-sheaths, and bursæ, further the aqueous and vitreous humour, and, lastly, the cerebro-spinal fluid. The third and last class of secretory fluids would be the secretions proper, such as the milk, the bile, and the urine. The two last specified kinds of secretory fluids possess either insignificant antibacterial power, or, in the case of the cerebro-spinal fluid, so far as is known, none at all.

Coming now to what has application to the case where microbes have invaded a secretory fluid, or a tissue which is bathed in, or a surface which is irrigated by, or a cavity which is filled with such a fluid, reflection will show that here antibacterial elements from the blood might be conveyed into the site of infection by one or other of two channels. It is *in primis* conceivable that drugs—as distinguished from antibodies—might be extracted from the lymph by the secretory epithelium and be excreted into the site of infection.

We know that urotropin passes in this way from the blood into the cerebro-spinal fluid and the urine; that methylphenolphthalein passes thus into the bile; iodides into the saliva; and various drugs into the intestinal secretions. But these are altogether exceptional occurrences, and even a moment's reflection will show that the odds against a pharmaco-chemical bacteriotropic agent or an antibody passing through an intact secretory membrane into, let us say, the tears, or the vitreous humour, or the synovial fluid, or any secretory fluid other than milk are so great as to be almost incapable of expression in figures.

Coming now to the alternative channel by which antibacterial elements contained in the blood might be transported into the secretory fluids, it will be appreciated that blood-fluids containing drugs or antibodies would in inflammation which involved destruction of secretory epithelium be transported by way of the lymph directly into the focus of infection. Furthermore, consideration will show that antibodies from the blood might also by the agency of negative pressure be drawn out into a secretory fluid. Reference is made later to the work of Speranski,[9] which shows a connexion with the treatment of tetanus and rabies that therapeutic substances in sera can by completely aspirating the cerebro-spinal fluid be drawn from the subdural spaces into the substance of the central nervous system. Turning to the leucocytes it is conceivable that these might, even through an intact (and a fortiori through a damaged) secretory membrane emigrate into a secretory fluid.

But with regard to all such direct transport of protective elements from the blood into secretory fluids the following requires to be specially emphasised. The blood fluids will always work at a great disadvantage when they are either diluted or frequently washed away by secretory fluids. And similarly leucocytes emerging into a secretory fluid will be eminently ineffective. Illustration of this is furnished by, for example, gonorrhœal infections of the conjunctiva, genital mucous membrane, and joints.

The foregoing will have made clear that the efficacy of antibacterial treatment by pharmaco-chemical bacteriotropic agents depends not only upon their entering into rapid destructive chemical combination with the microbes and exclusively with these, but also upon the chemical agents in question being transported from the blood into the lymph and from the lymph into the secretory fluids. It has further appeared that the failures of pharmaco-chemical—and the same holds good of immuno-chemical treatment—are, as it would seem, more often imputable to a default of convection than to a default in the chemical constitution of the therapeutic agent employed.

And the mental picture we have just arrived at will be seen to fit in well with clinical observation which teaches that antibacterial treatment is wont to be more effective early in an infection—that is, when the microbes still lie open to attack in the lymph and the circulating blood—than in the later phase when they have entrenched themselves in the phylactic foci. We have in the domain of pharmaco-therapy illustration of this in the fact that salvarsan when given early in syphilis does in many cases extinguish the infection while, when given later, it very often fails to effect this. Further striking illustration of the therapeutic principle here in question is furnished by the fact that bismuth [10] given to animals inoculated with the spirochætes of hæmorrhagic icterus will, if employed soon after the inoculation, extinguish the infection, while it fails to do this when given after the lapse of a few days. This is the exact reverse of what happens with sanocrysin. The experiments of my fellow-worker, R. M. Fry,[11] have shown that this agent, which was reputed to enter into destructive chemical combination with tubercle bacilli, does not, even when employed in concentrations much stronger than would be possible in the body, interfere with the growing out of tubercle bacilli into colonies in the blood in vitro. And further, the experiments of Madsen and Morch [12] have shown: *first*, that sanocrysin does not, when given with or immediately after an injection of tubercle bacilli in any way hinder the march of the infection; and, *secondly*, that the drug given at a later date, and employed in strictly adjusted doses, saves a certain number of animals. The former of these findings is in obvious accord with the results obtained by Fry. The latter is, no doubt, explained by the fact that sanocrysin induces, like tuberculin, an infractive inflammation of ecphylactic niduses—such infraction being followed in non-resistant men and animals by a disastrous tubercular septicæmia, but no doubt in men and animals whose blood has been fortified by auto-immunisation,[13] by a destruction of the tubercle bacilli carried into the circulation.

The general principles which should inform all antibacterial treatment having now been set forth, our next task must be to consider the method by which antibacterial elements which may be present

in the circulating blood can be brought into operation upon infecting microbes in ecphylactic niduses.

We may conveniently begin our consideration of these methods by considering what we here require by way of terminology. We require, first, a general term which will embrace every kind of procedure which brings destructive agencies into operation upon microbes which would in the natural course of events escape unscathed. The term *kataphylaxis* will, perhaps, supply what is here wanted. We may further desire to distinguish *kataphylactic procedures* into: (*a*) *leucocytagogic procedures* which bring leucocytes, and (*b*) *seragogic procedures* which bring serum into operation. And, finally, where we have in mind the bringing of pharmaco-chemical elements into operation in regions which are sequestered from the blood stream, we may employ a term which is already in use, the term *kataphoresis*.

We may now take up the study of the methods of bringing pharmaco- or immuno-chemical substances into operation upon microbes which have elaborated ecphylactic niduses for themselves within the domain of the vascular system.

We have seen that opportunity for the establishment of ecphylactic niduses within the domain of the vascular system is provided, *first*, when the blood current is arrested by intravascular coagulation; *secondly*, when capillaries in the skin or elsewhere are closed down by the contraction of muscle cells in their walls; and *thirdly*, when blood which has been in circulation is brought to rest in the diverticula of the spleen. In the first case all that can be done is to administer citric acid [14] with a view to diminishing blood coagulability and preventing the reinforcement of the primary clot by a series of supplementary clottings.[15] When by timely intervention those reinforcements of the clot have been warded off, the lumen of the vessel will be rendered patent by the normal retraction of the fibrin and the washing out of the red corpuscles which constitute what we might call the "stuffing" of the clot. It will be obvious that when this packing of red corpuscles has been removed dissolved antibacterial elements both chemotherapeutic substances or antibodies, and also efficient leucocytes—supposing always that we have these in the circulating blood—will come into operation upon the microbes which have been sheltering within or behind the clot.

In the case where microbic colonies are lodged in the capillaries of the skin, these can be opened up by heat and other vasodilator influences. And such opening up will, in the case where antibacterial substances are circulating in the blood, result in these being let in upon the microbes, while the bulk of these will be swept out into the circulating blood and will, when that blood is bactericidally potent, be destroyed there. Let us call this *infractive and korethric* treatment (*korethric* from korethros—a besom or sweeping brush).

Ecphylactic niduses in the spleen require, like those in the capillaries, korethric treatment. But here instead of producing dilatation we require to produce contraction of the spleen. We might here avail ourselves of the fact brought out by Barcroft that vascular changes which call for an increased volume of circulating blood (changes such as general cutaneous vasodilatation and the dilatation which accompanies muscular action) produce a reflex contraction of the spleen. Or again, we might, making use of other physiological data furnished by Barcroft, produce a reflex contraction of the spleen by cutting down the respiratory value of the blood by administering carbonic oxide, or better (for this will be innocuous) ordinary carbonic acid gas. And, lastly, we might employ adrenalin, or again certain other pharmaco-chemical substances studied by Binet, Cardot, and Fournier [16] and so produce direct in lieu of reflex contraction of the spleen.

It is interesting to note in connexion with the exhibition of adrenalin that it has in cases of latent malaria been successfully employed for contracting the spleen and evacuating into the circulating blood (for purposes of diagnosis) crescents and other malarial parasites which have, as the common formula says, "retired from the superficial circulation into the spleen." It will be recognised that the parasites in question are not, in point of fact, organisms which have "retired" into the spleen, but organisms which (and the same happens to typhoid bacilli in typhoid fever, and spirilla in relapsing fever) have been able to establish favourable conditions for growth in the stagnant blood of the spleen, when those organisms which continued to circulate in the blood were killed.

A further point of interest in connexion with the administration of adrenalin in these cases is that very severe attacks of malaria are reported to have been produced by the treatment.

We have here again illustration of the fact that it is a sinister procedure to sweep microbes out from the foci in which they are lying quiet into the general circulation, unless we have ascertained before we do so that the blood in the general circulation has become bactericidally potent, or unless antibodies or pharmaco-therapeutic remedies have been introduced into the blood in order to prevent a generalisation of the infection. The risk of disseminating microbes into blood not capable of killing them was long ago abundantly illustrated in connexion with Koch's treatment of phthisis by tuberculin. It has also recently been illustrated in connexion with the administration of sanocrysin to tuberculous patients.

We pass now to consider the kataphylactic procedures which can be brought into application upon ecphylactic foci situated in lymph-infiltrated tissues and secretory fluids. Let us distinguish these into procedures which are both leucocytagogic and seragogic, and into those which are seragogic only.

Procedure.	*Physiological action.*
(1) Induction of active hyperæmia and inflammatory irritation.	Leucocytagogic and seragogic.
(2) Induction of passive congestion by Bier's bandages.	Seragogic only.
(3) Induction of œdema ex vacuo by depletion and evacuation of the local focus of infection.	Seragogic, and possibly leucocytagogic.
(4) Lowering of the general blood coagulability.	Seragogic only.
(5) Induction of Arthusian inflammation.	Leucocytagogic and seragogic.
(6) Employment of albumino-tractor (intertracting) agents.	Seragogic only.

The principles of the first three of these procedures and the methods of exploiting them being, it may be assumed, universally familiar, it will be unnecessary to say anything about them here, except only again to refer to the brilliant work of Speranski,[17] which shows in connexion with the treatment of rabies and tetanus (and the same would probably apply to all other cerebral infections) that antimicrobic and antitoxic elements contained in sera introduced into the subdural space can by the agency of negative pressure (established by the complete evacuation of the cerebro-spinal fluid under anæsthesia) be drawn into the substance of the central nervous system.

With regard to the principles of the three last kataphylactic procedures these may with advantage be briefly elucidated.

Lowering of the General Blood Coagulability.—showed in a series of papers now many years ago that urticaria, chilblains, physiological albuminuria and anasarca could all be brought under the general heading of serous hæmorrhage, and that such serous hæmorrhage, or to give it its more usual name, excessive serous effusion, is correlated with diminished blood coagulability and is aggravated by the exhibition of citric acid and other agents which reduce blood coagulability, and alleviated by calcium chloride

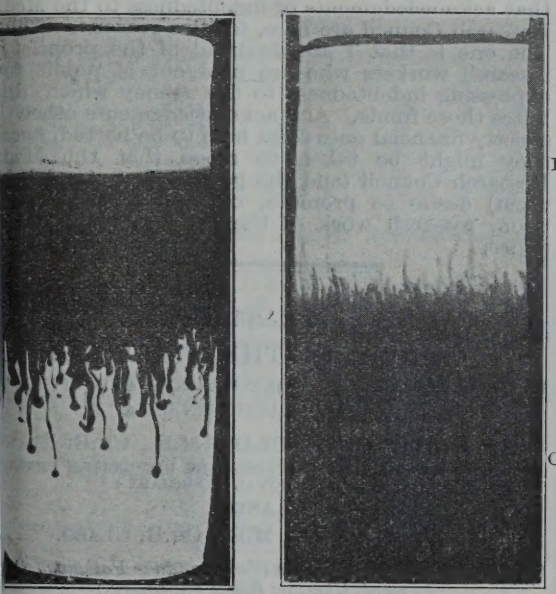
nd other agents which increase blood coagulability.[18] onsideration will show that the principle here involved as application also to the treatment of bacterial nfection in the tissues and more specially to pharmaco- nerapeutic treatment. For manifestly there will e better prospect of bringing a drug into operation n the tissues if the blood at the time the drug is ntroduced is in a state to furnish a maximum of erous exudate.

It will be interesting in this connexion to hark back o the paradox encountered earlier in this paper, the aradox that syphilitic infection is not infrequently

hotographs of Vertical and Horizontal Intertraction.

FIG. 1. FIG. 2.

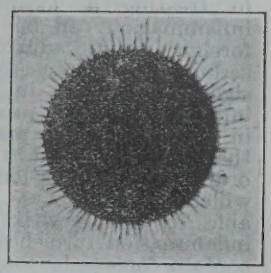


. 1.—Here a layer of serum coloured with eosin (B) has been uperimposed upon a layer of a specifically heavier (10 per ent.) salt solution (C). Beginning almost instantaneously the erum is rapidly drawn down (*descending intertraction*) into he salt solution in the form of pseudopodial streamers. bove the layer of coloured serum (B) the vessel is filled with ater (A). Into this after long waiting the serum gradually iffuses spreading upwards not in streamers but in the form f a level horizontally dispersed wavefront.

. 2.—Here uncoloured serum (B) is superposed upon a layer f coloured 10 per cent. salt solution. (C) After the lapse of a ew minutes the salt solution is drawn up into the serum ascending intertraction) again in the form of polypoid reamers.

cessfully extinguished by following out that oretically unsound procedure which Ehrlich called herapia sterilisans fractionata. Let us see whether s problem can now be cleared up. Partial illumina- n may perhaps come to us when we reflect that a g taken in repeated doses will, according as erent tissues and different portions of the body pen, after the incorporation of the dose to be own into activity, be determined each time to ifferent anatomical region. And on the doctrine chance there will in the case where many doses administered be a prospect of the drug being ied in turn into all such foci of infection as are accessible. From this clinical advantage is naturally to be expected. But there is superadded to this factor of chance another physiological factor which is operating steadily, in the direction of making the sequent doses of salvarsan more and more effective. Salvarsan, given in repeated doses, regularly and markedly lowers the coagulability of the blood. One can immediately see that this is bound to promote a freer flow of arsenic-carrying lymph through the tissues.

FIG. 3.

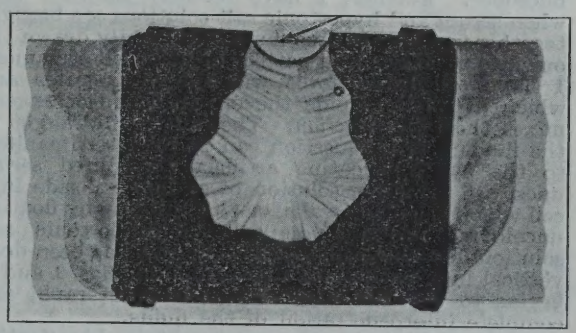


Here a disc of filter paper which has been fastened by a pellet of plasticine to the surface of a paraffin-rimmed cover-glass and has been impregnated with coloured serum has, after firm blotting, been floated inverted upon a 4 per cent. salt solution. Into this the serum is drawn out from the filter paper in the form of an ever-lengthening system of streamers.

Now, if it is this—and it may well be this—that renders the theoretically unsound therapia sterilisans fractionata practically effective, it would be well to consider whether it would not be more rational to begin the treatment of syphilis by administering citric acid in quantity sufficient to diminish blood coagulability and increase with this serous effusion all over the body. One might then hope to accomplish as much by a first dose of salvarsan as is by the ordinary procedure accomplished after a long series of doses.

Induction of Arthusian Inflammation.—It was shown by Arthus [19]—and our understanding of the subject has been much extended by Opie [20]—that when repeated doses of a foreign serum are hypodermically or intradermally inoculated, the third or fourth of the series (the first two having no visible effect) will be

FIG. 4.



Here a piece of specially dense filter paper has been cut out in such a way as to represent an axial section of a wound cavity. The artificial wound section thus obtained is then impregnated with coloured serum. It is then interpolated between a couple of microscopic slides and these are clamped together. This done any serum which may have escaped into the cavity is carefully evacuated, and the cavity is then filled with an ordinary 5 per cent. salt solution, or better with serum containing 5 per cent. of salt. As soon as this has been done the coloured serum is drawn out in streams from the encasing walls into the saline solution occupying the cavity of the artificial wound.

followed by some local œdema, the fifth and sixth by a more pronounced œdema, and the later injections not only by serous effusion but also by emigration of leucocytes and often by localised necrosis. It has been shown that the development of these phenomena is correlated with an elaboration of precipitins in the blood of the injected animal, and that the inflammatory reaction which follows incorporation

[19] Comptes Rendus Soc. de Biol., 1903, p. 817. Ibid., 1478.
[20] Tuberele, October, 1925. Journal of Immunology, vol. ix. No. 4, 1924. Journal of Exp. Med., 1924.

of the foreign serum is probably due to its precipitation at the site of injection. An Arthusian reaction, quite similar to that obtained in the manner just described, can be produced by injecting into the blood of the animal which is to receive local inoculation of a foreign serum an antiserum to this. And again—and this is a procedure which might perhaps be employed in treating a localised infection—an Arthusian inflammation can be produced also by injecting a foreign serum admixed with precipitating antiserum. Let us note—for the fact may have therapeutic significance—that in all varieties of Arthusian inflammation the products of inflammation differ in a respect which may render them more effective than those furnished in ordinary inflammation. While ordinary inflammation furnishes a serous effusion which contains sparse leucocytes and is itself favourable to the growth of serophytes, an Arthusian inflammation furnishes a serous effusion which may contain copious leucocytes and is (it has presumably become so probably by virtue of a liberation of bactericidins from leucocytes) definitely bactericidal. Consideration will show that this method may in the future be found to have therapeutic applications. A mixture of serum and antiserum, or possibly an antihuman precipitating serum by itself, is the sort of agent which could be injected not only into an infected tissue or a neoplasm, but also into an infected serous effusion or secretory fluid. I have specially in view infections of the central nervous system and not alone syphilitic infections, but others like encephalitis lethargica, infantile paralysis, and rabies.

Employment of Albumino-tractor (Intertracting) Agents. It was long ago shown by Heidenhain that strong solutions of sodium chloride and other salts and also of sugar functioned when introduced into the blood as powerful lymphogogues. In connexion with these same solutions, I have, from 1900 onwards, and in particular during the war, been pointing out that they, when introduced into wounds or sinuses, operate as powerful local lymphagogues causing a welling up of serum, and with this a cleansing of these niduses of infection from all but serophytic microbes. Further, I have recently shown [21] that when serum and hypertonic salt solutions are brought together in vitro the two fluids are rapidly drawn the one into the other in a pattern of polypoid streamers. I have called the force which here operates and which draws the fluids the one into the other and mixes them *intertraction*. The mutual indraught of the fluids here in question can be rendered manifest to the eye by floating artificially coloured serum upon a 5 per cent. solution of sodium chloride in a cell which has plane walls, or alternatively by floating uncoloured serum upon coloured hypertonic salt solution in such a cell. As soon as this has been done vertical intertraction, as represented in Figs. 1 and 2, begins to manifest itself in the form of rapid and complete interpenetration of the fluids.

Horizontal intertraction can be obtained by floating upon a 4 per cent. salt solution a disc of filter paper fixed upon the lower surface of a paraffined rimmed cover-glass, and then impregnated with coloured serum. This gives appearances such as are depicted in Fig. 3.

A further experiment which illustrates the intertraction which is produced by the introduction of hypertonic salt solution into wounds is illustrated in Fig. 4. Here a dense filter paper which has been cut to represent the profile of a wound in section has been soaked in coloured serum and has been interposed between two slides. These arrangements made, the slides are clamped together, any superfluous serum in the cavity of what we may call the artificial wound is removed, and then there is filled into that cavity either hypertonic salt solution or better serum which contains 5 per cent. of salt. This done, the coloured serum which impregnates the paper is seen to flow out in the form of streamers in the wound cavity.

[21] Wright: Proceedings of the Royal Society B., vol. xcii., 1921; A, vol. cxii., 1926; A, vol. cxiv., 1927.

Consideration will show that hypertonic sa solutions can find useful kataphylactic applicati not only as local seragogues directly introduced in the wound for cleansing it from non-serophyt infection, but also when they are injected into t blood. They will then, as Heidenhain's classic experiments showed, function as powerful gene seragogues. And thus employed they will, in t case where the circulating blood contains chem therapeutic elements (immuno- as well as pharmac therapeutic elements) be bound to carry these in rapid stream through the tissues, achieving ve rapidly that transport of antibacterial elements in the foci of infection which will, even when it is favour by reduced blood coagulability, be accomplished or very slowly.

In concluding, I may, perhaps, venture to expla that acknowledgments of indebtedness to the Medi Research Council are here, for two reasons, withhe The one is that I am doubtful of the propriety research workers who are paid out of public fun expressing indebtedness to the agency which dist butes those funds. And acknowledgments other th strictly financial ones seem here to be barred, becau they might be taken to mean that the Medi Research Council (and the powers that stand behi them) desire to promote, or even look favourab upon, research work of the type embodied in th paper.

A CASE OF
CANCER OF THE PANCREAS,
WITH METASTASES IN BONE-MARROW AND LIVER, A MEGALOBLASTIC ANÆMIA.

BY J. STEVEN FAULDS, M.B., CH.B. EDIN.,
ASSISTANT PATHOLOGIST AND ASSISTANT DISPENSARY PHYSICI GLASGOW ROYAL INFIRMARY;
AND
W. MACKAY, M.B., CH.B. GLASG.
(*From Prof. W. K. Hunter's Wards and the Pathology Dep ment, Glasgow Royal Infirmary.*)

IT is now recognised that metastases in bo marrow, secondary to cancer of certain abdomi viscera, may produce a blood picture resembling m or less closely that of pernicious anæmia. Such ca are not common and, when they do occur, it seems us that they should be carefully investigated, in hope that they may shed some light on the origin the megaloblast and incidentally on the pathogen of pernicious anæmia itself. We wish, therefore, place on record the following case.

A male patient, aged 50, a labourer, was admitted hospital on Sept. 13th, 1925, complaining of general we ness and pain in the chest. Six weeks before admission noticed that he was losing strength, and within a fortni he was obliged to give up his employment. Further, in four weeks previous to admission he lost 4 st. in weig his appetite was poor, and he had attacks of sickness vomiting. On one or two occasions his doctor had covered albumin and sugar in his urine. There was history of sore tongue, hæmorrhage, thirst, or polyuria, there was no indication of disease of the central nerv system.

On admission he was emaciated and looked ill. mucous membranes were pale, the skin had a slight yellow tint, and he complained of vague pains in the right side the chest. The heart sounds were of poor quality, but murmurs were audible, and the blood pressure was There was slight lack of resonance with prolongation expiration and increase in vocal fremitus at the apex of right lung, while some scanty fine crackles were heard both apices. The teeth were carious and the gums swo and pale, but the tongue was clean. There was no abdomi pain, and the liver and spleen did not seem to be enlarg The urine did not contain any abnormal constituent.

During his stay in hospital there was no sickness vomiting, but the patient suffered from loss of appetite great progressive weakness. Tenderness and a degree resistance developed in the epigastrium and the liver increa very rapidly in size, the lower border ultimately reach

low the umbilicus in the middle line. The spleen was ver palpable, but, on percussion, as time went on, the enic area seemed to extend forward to the costal margin. actional test-meals on two occasions showed the presence free hydrochloric acid in normal amount. X ray examina- n suggested some deformity at the pylorus, associated th delay in the emptying of the stomach.

Coincident with the enlargement of the liver a slight lging became noticeable in the right infra-axillary area. finite pain was complained of over the ribs in this region th marked tenderness over the sternum and ribs. Towards end the patient became greatly emaciated, he sank idly, his skin assumed a deeper yellow tinge, and the n in the ribs and sternum increased. He died on v. 28th, 1925, 11 weeks after admission. There was ver any pain in the long bones.

Throughout his stay in hospital the patient had a fairly found degree of anæmia. Table I. shows the red blood- l counts.—

e blood-sugar on admission was 0·15 per cent. The ermann reaction of the blood was negative. H. van Bergh's indirect quantitative reaction showed the ubin in the blood to be less than 0·25 units. Fouchet's for bilirubin in the blood was negative.

Report of Post-mortem Examination.

orax: On opening the thorax a glandular mass was d in the mediastinum surrounding the trachea and chi and the great vessels arising from the aortic arch. equent examination proved that it was a secondary vement of the mediastinal glands by carcinoma. The of the left lung was also involved by a spread along peribronchial lymphatics from the mediastinal mass, throughout the substance of both lungs there were erous small nodules of secondary carcinoma. There a few very small nodules present on the parietal pleura the line of the angles of the ribs on the left side. The presented no abnormalities. Abdomen: The liver normously enlarged, weighing 162 oz., the parenchyma largely replaced by carcinomatous nodules of varying and size. The larger nodules were of long standing ng from the umbilication present, but the majority ed to be of recent date, since they varied in size from n. downwards. The hæmosiderin reaction was defi- positive and comparable to the reaction found in ses associated with rapid blood destruction.

emosiderin granules were found, on microscopic exami- n, to be present both in the liver cells and also in the helial cells. They were fine in character and scattered more or less uniformly throughout the liver cells. The reaction was not so intense as that found in many cases of pernicious anæmia where the hæmosiderin is present in large amounts. Extensive permeation of the liver substance had taken place with minute collections of malignant cells. The spread was up the biliary lymphatics, and no embolic cells were found in any of the blood-vessels. No evidence could be found of hæmatopoiesis in the liver, either megaloblastic or normoblastic, in the section examined. Spleen: The spleen was considerably larger than normal. Throughout the organ there was a diffuse invasion by malignant cells, varying from groups of 3 or 4 up to masses the size of Malpighian bodies. Embolic masses were to be seen in the arteries and veins spreading throughout the splenic sinuses. Nucleated red cells resembling normoblasts and eosinophilic leucocytes were seen in abundance. Endothelial cells containing ingested red blood corpuscles and altered hæmoglobin were present in considerable numbers throughout the sections.

Pancreas: The pancreas was found to be firm and fibrous. Situated in the substance at the junction of the body and head was a hard tumour about the size of a walnut, which was taken to be the primary tumour. Microscopic examination showed it to be an adenocarcinoma. The islets of Langerhans were prominent and congested, and seemed to be more abundant than normal. Kidneys: There was a chronic interstitial nephritis present in both organs. The bone-marrow from the long bones was examined and in all there was decided vascular reaction. The entire length of the shaft of the bone was filled with marrow of a maroon colour, and the appearance simulated that found in pernicious anæmia. Peculiar opaque gelatinous-looking areas were scattered throughout the marrow of all the bones which microscopic examination showed to be secondary deposits of adenocarcinoma. The bony trabeculæ normally present in the interior of the shafts of the bone were completely absorbed, and there was erosion of the inner wall of the compact bone, thereby increasing the available space for blood-cell production.

To such an extent was the left humerus weakened that during manipulation at the post-mortem it fractured. On microscopic examination the bone-marrow was in no case found to be normal, showing an erythroblastic reaction, with varying amount of replacement with adenocarcinoma. Films were made from the marrow of all the long bones and two of the ribs. Pieces of marrow were also taken, fixed in formalin, embedded in paraffin, and stained by Pappenheim's panoptic method, Leishman, eosin methylene-blue (Mallory), hæmalum and eosin.

Examination revealed (1) normoblasts; (2) megaloblasts, these being nucleated red cells of a large size with finely reticulate nuclei and a cytoplasm of an oxyphilic or polychromasic reaction, many of which were in a state of mitosis; (3) megalocytes showing both oxyphilic and polychromasic cytoplasm; (4) myeloblasts; (5) myelocytes, showing both oxyphilic and basophilic granules; (6) large numbers of adenocarcinomatous cells of spheroidal type. These malignant cells were situated in clusters, always in close relationship with one of the larger arterioles, but in no case were they found actually inside a blood-vessel. In some situations, however, they were enclosed by a fibrous tissue stroma lined with a delicate endothelium. This had been formed in all probability by the distension of the marrow sinuses with malignant cells. In other situations there was a diffuse infiltration of the marrow with malignant cells, and it is interesting to note that there was no special reaction on the part of the marrow in the immediate neighbourhood of the clusters of invading cells in the form of a megaloblastic reaction—i.e., in no place could the type of marrow cell immediately surrounding the clusters be considered to be different from that found throughout the marrow in general.

Discussion.

When the patient came under observation the diagnosis was not quite obvious. The progressive weakness, anorexia, sickness and vomiting, together with the anæmia and the blood picture, and the absence of any definite localising sign of neoplasm or other cause of anæmia, were suggestive of pernicious anæmia. However, the rapid enlargement of the liver, the presence of large numbers of nucleated red cells and myelocytes in the circulation, associated with pain over the ribs and sternum, suggested the diagnosis of malignant disease with bone metastasis. The presence of free hydrochloric acid in the stomach, and the result of the van den Bergh reaction, tended to confirm this diagnosis.

A striking feature of the case was the presence of large numbers of nucleated red blood corpuscles in the circulation and, in view of the conclusions of

Piney regarding the specific character of the megaloblast, special attention was directed to these cells. Piney holds that the true megaloblast has a finely reticulated nucleus, and that this specific cell is found only in pernicious anæmia and familial icterus. He maintains that it is formed in the liver as a fœtal remnant. The remaining nucleated red cells found in the circulation in various diseases he differentiates into two types: (1) macronormoblasts, which have cart-wheel nuclei and polychromasia of the cytoplasm, and (2) normoblasts. One hundred nucleated red cells were examined from 14 dry-blood films, eight films being stained with Leishman's stain and six with Jenner's stain. The measurements were made with eyepiece and stage micrometers. Forty-seven of the cells had average diameters of 10 microns or over. The smallest nucleated red cell had an average diameter of 7·2 microns, while the largest, two of which were observed, had average diameters of 12·75 microns.

In a general way, the size of the nuclei varied directly with the size of the containing cell. The largest, measuring 8·5 microns, were found in cells of 11 and 11·9 microns in diameter, while the smallest nucleus, 3·5 microns in size, was found in a cell of 10·2 microns in diameter. The largest cell, 12·75 microns, had a nucleus of 6·8 microns, and the smallest cell, 7·2 microns, a nucleus of 5·9 microns.

Great variation in structure was observed in the nuclei examined. The majority showed some degree of condensation of the basichromatin. In 15 there was definite pyknosis such as is seen in the normoblast, in 9 the basichromatin was arranged so that the structure of the nuclei resembled the "cart-wheel" type, while in 52 nuclei the condensation varied in degree from a mottled or blotchy arrangement to a stippled or granular appearance, and the formation of a rather coarse openwork reticulum. In two nuclei the basichromatin had the arrangement of a tangled skein, in six cells the nucleus was finely reticulate in character, and in another cell the nucleus was in chromosome formation. Fifteen nuclei showed fragmentation or segmentation. The six cells showing the finely reticulate appearance varied from 8·5 to 11 microns in average diameter. The cytoplasm of five of these cells was polychromasic, while in the sixth cell the cytoplasm stained faintly with eosin. Generally it was noted that the nuclei showing definite pyknosis, or some degree of pyknosis, were most often found in cells having eosinophil cytoplasm, yet such nuclei were also seen in cells showing polychromasia.

It is difficult to classify these nucleated red cells into clear-cut types, as the great variations in the size of cell, nuclear structure, and associated staining reaction of the cytoplasm seemed to represent different stages in the life of the nucleated red cell. The six cells already mentioned showing finely reticulate nuclei were thought to resemble those megaloblasts described by Piney as being specific to pernicious anæmia. Accordingly, these six cells, together with the other large cells having a large mottled, reticulate, or openwork nucleus, are regarded as true megaloblasts and similar in all respects to those found in the circulation in pernicious anæmia.

As regards the origin of the megaloblast microscopic examination failed to reveal the presence of blood-forming tissue in the liver. Megaloblasts were very numerous in the bone-marrow, and many were observed in the process of division. The megaloblast is not normally present in the marrow, but in this instance it is considered that the bone-marrow was the site of origin of this cell as well as the other nucleated red cells found in the circulation.

The possible relationship of this megaloblastic marrow to the tumour metastases is a question of some interest. Ehrlich has suggested that a toxin derived from the cancer cells might supply the stimulus which determines this change in the marrow. In this connexion the work of Russell is of interest. He showed that in mice the transplantation of carcinomatous cells could produce a sarcomatous change in the connective tissues of the new host. He quot a case, reported by Schmorl, as illustrating the occu rence of a similar process in the human subject, wher in a man who died from carcinoma of the prostat secondary deposits were found in the skeletal syster In the bend of the right femur one of the deposi was surrounded by an extremely cellular mesoblast tissue of a sarcomatous type, this malignant chan being induced by the carcinomatous cells. Russe also mentions the conclusion of Axhausen wh attributed this change to irritation, presumably of chemical nature, of the stroma by the cancer cells.

The human marrow is a mesoblastic tissue, and our case just recorded it has taken on an embryon type of growth, shall we say, in response to the inv sion of cancer cells. Microscopic examination, hov ever, failed to show that the megaloblastic reactio was confined to the vicinity of the tumour metastase and so if the cancer cells were producing a stimulu they would seem to have done so at a distance—i.e the tumour toxins must act in a diffuse manner.

The character of the blood, marrow, and th hæmosiderin deposit in the liver in our case presen an appearance very similar to that met with in cas of pernicious anæmia where presumably there is al a toxin or some other form of stimulus acting o the bone-marrow and so inducing the megaloblast reaction. If this is the case, it would suggest th conclusion that the marrow change in the presen of cancer metastases and in pernicious anæmia is th primary episode and that the hæmolysis and hæm siderosis are secondary events. This is Ehrlich original idea and it has the support of many oth hæmatologists.

We acknowledge gratefully the invaluable assistan and helpful criticisms of Prof. W. K. Hunter an Prof. John H. Teacher in whose departments th work was carried out.

THE EFFECT OF VARIOUS CARBOHYDRATE FOODSTUFFS ON THE BLOOD-SUGAR IN DIABETES.*

BY W. W. PAYNE, M.B., B.S.LOND.,
BIOCHEMIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

IT has been known for a long time that the bloo sugar rises after a meal containing carbohydrat It is probable that the less the pancreas is ove stimulated by a raised blood-sugar, the better the chance of a certain amount of recovery, or, at an rate, of stopping the progress of the disease. To preve an excessive rise in the case of diabetic subjects, th carbohydrate in meals is restricted, but at prese the custom is to regard all foodstuffs which conta the same amount of carbohydrate as equivalent their effect. Such a view can only be definite proved if the same variations of blood-sugar a found in a patient after meals containing vario carbohydrate foodstuffs, the total amount of carb hydrate being kept constant.

Owing to the laboriousness of the work, it has n been found possible to examine very many of th carbohydrate foodstuffs suitable for diabetic patient though some of the most important have been teste

Method.—The method adopted was to give diabetic subject a series of test breakfasts. On of the breakfasts consisted of two eggs, 1 oz. butter, and tea, while the carbohydrate foods be examined were added to the other breakfast The blood-sugar was estimated before and at quart

or half hourly intervals for three to four hours afterwards. As a series of daily tests were required, the choice of a subject was of some importance. A mild case was necessary in order to avoid giving insulin before the meal; the whole of the insulin required was given at night and in quantity sufficient to keep the fasting morning blood-sugar within reasonable limits (preferably about 0·1–0·12).

Cooking.—The rusks used were made by baking 1 oz. of bread in an oven till light brown in colour.

hows rise in blood-sugar after non-carbohydrate meal and also an almost similar rise preceded by a fall when the same meal plus 1 oz. bread was given. The base-line represents the initial fasting blood-sugar.

he carbohydrate content was estimated in another iece baked at the same time. The oatmeal was oiled for four hours, the turnips were boiled and ashed, the excess fluid being strained off. The urrots and potatoes were boiled 50 min. and the ater strained off. The tomatoes were fried or baked a tin. The cabbage was steamed for one hour.

In two subjects the response of the blood-sugar the meals was irregular. In these the following vo points were noticed: (1) A rise in the blood-sugar as obtained when the test breakfast without carboydrate was given. (2) When a meal containing

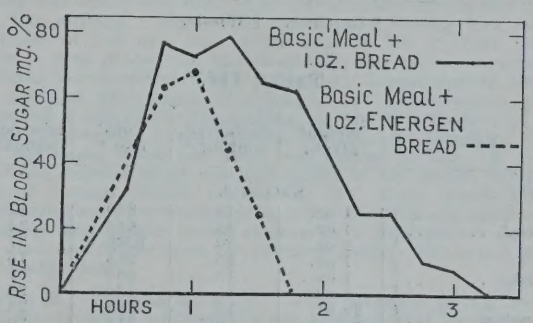
bohydrate was given the first blood-sugar taken f an hour after a meal, instead of showing the usual nite rise, was either the same as, or actually lower, n the initial fasting blood-sugar (Fig. 1). Cammidge obtained similar results and has correlated them h variations in the acid-base balance due to tion of first acid and the alkaline digestive juices. hould be noted that in only two out of the seven s examined here was such a result obtained, le presumably all secreted acid and alkaline stive juices. In the case of these patients it was, ever, considered that some factor other than the amount of carbohydrate taken was involved, and the results were not used in this investigation.

With the first two subjects the amount of carbohydrate food given was such as would contain 15 g. of carbohydrate in its uncooked state, judged according to the food tables of Atwater and Bryant. This is the usual way of ordering the food in a diet. It was then realised that it would be more satisfactory to know the exact amount of carbohydrate given, and in subsequent experiments an estimation of the carbohydrate content was made on a sample of the food after preparation. Later on estimations were made on the cooked food used in these early experiments, the methods of cooking being repeated as closely as possible, but the values obtained in the case of potatoes and carrots varied so much that only a rough approximation of the actual carbohydrate given could be made. Table I. illustrates this point. Fortunately, the bread used, which came from the hospital bakery, was found to be of almost constant composition.

In comparing results, both the height and the duration of the rise of blood-sugar should be considered.

FIG. 2 (Case 5).



Shows rise in blood-sugar after the test-meal plus 1 oz. bread and after the same meal plus 1 oz. Energen bread. Both meals contained almost equal amounts of carbohydrate. The area between the curve and the base-line represents the total rise. The base-line represents the initial fasting blood-sugar.

For the sake of convenience this is referred to as the total rise. The amount of carbohydrate given must also be considered and the total rise per gramme of carbohydrate determined by dividing the total rise by the number of grammes of carbohydrate given. The total rise referred to above is measured from the area between the blood-sugar curve and the base-line drawn through the fasting value, but the following method of calculating the total rise adopted, while not absolutely accurate, is sufficiently close for the purpose. The rise of blood-sugar over the initial value expressed as milligrammes per cent. is found for each quarter hour after the start of the meal, and the sum of these is taken as the total rise. If, for any reason, the estimation was missed at any given quarter hour the average of the preceding and succeeding quarter hours was used. In a few cases where the blood-sugar had not returned to normal when the experiment was stopped, an addition was made, based on rate of fall in progress at the end of the experiment; in no case did this addition make any substantial difference to the results.

Results.—Table II. gives the figures obtained in subjects 1 and 2, while Table III. gives those in subjects 3, 4, and 5. In subject 4 the experiment was inadvertently carried into a menstrual period. The fasting blood-sugar in three experiments were 0·139, 0·140, and 0·137, against 0·109, 0·104, and 0·108 in previous experiments. As this would indicate a temporarily decreased tolerance, the results are not strictly comparable. In order to be able to bring the results together, the average rise per gramme with 1 oz. of bread in each subject has been called 100, and the remaining results expressed as a percentage of this, as shown in Table IV.

Discussion.

It will be seen from Table IV. that many carbohydrate foods give a definitely smaller rise per gramme of carbohydrate than does bread. With the exception of tomatoes and turnips, all fruits and vegetables tested gave a rise of about 50 per cent. or less. Of the cereal foods used, oatmeal showed a figure slightly below 100 per cent. on the one occasion it was examined. Rusks gave a varying response, but on the whole showed a definitely smaller rise per gramme than bread. Energen bread, which contains as much carbohydrate in an ounce as bread, gave, in three experiments on one subject, a rise of about half that of bread.

The cause of this lessened rise might be due either to failure to absorb the carbohydrate or to the rate of absorption being slower. Evidence on this point was obtained by examining the fæces in subject 5. On a diet containing 1½ oz. of bread, but no vegetables, 0·3 g. of carbohydrate was lost per day in the fæces. When 1½ oz. of Energen bread was given instead the amount of carbohydrate lost was 0·37 g. There was thus no failure in absorption. This was further confirmed by comparing the blood-sugar level of the patient when on the two diets.

Bread.	Blood-sugar per cent.	Energen bread.	Blood-sugar per cent.
May 4th, 1927—		April 27th, 1927—	
11.15 A.M.	0·084	11.10 A.M.	0·099
3.10 P.M.	0·086	—	—
5.30 P.M.	0·107	5.30 P.M.	0·109
May 9th, 1927—		April 29th, 1927—	
11.30 A.M.	0·083	11.15 A.M.	0·086
3.5 P.M.	0·091	3.10 P.M.	0 097

It will be seen that there is practically no difference between the two sets of figures, suggesting that the same amount of carbohydrate was absorbed in each case. It is possible in the case of uncooked fruit and vegetables that, owing to their structure, a certain amount of carbohydrate is not absorbed.

Conclusion.

1. Certain carbohydrate foodstuffs cause less rise of the blood-sugar per gramme of carbohydrate than do others. (2) This is probably due to a slower rate of absorption.

My thanks are due to Dr. E. P. Poulton for much advice and practical help, and to Dr. Robert Hutchison and Dr. Poulton for permission to use their patients for the experimental work. I also wish to thank the various subjects who cheerfully submitted themselves to the discomforts of the experiments.

AN OPERATION FOR THE ALLEVIATION OF DEAFNESS.

BY VINCENT NESFIELD, F.R.C.S. ENG.,

MAJOR, I.M.S. (RETD.); OPHTHALMIC SURGEON, QUEEN'S HOSPITAL FOR CHILDREN; LATE SURGICAL SPECIALIST, MHOW DIVISION.

IN 1919, while serving in the Indian Medical Service and acting as surgical specialist of the Mhow Division, I was approached by many people suffering from deafness, and was unable to help them.

One day I found in the cantonment hospital in Jubhulpore a fine old Sikh of 65 or more lying on the operating-table; he refused to move until I had operated on him, as this was his lucky day. About a month previously I had extracted both his cataracts and he could see perfectly, so he believed that the cure of his deafness was an easy matter. I had many times refused to operate, explaining that the eye was on the surface, and the organ of hearing hidden at the bottom of a long narrow canal embedded in the skull. It was these discussions that finally suggested to me mind the operation here described.

He was very importunate and had indeed taken an oath of starvation unless I operated, and so I asked

he doctor babu to give him chloroform and operated on both ears. The man made an excellent recovery, and went home both seeing and hearing. This brought me such a stream of similar sufferers that I did not know how to cope with them.

The fundamental idea of the operation is simple. When deafness is due to obstruction of the Eustachian ube the treatment is to make a new passage leading rom the exterior into the cavity of the middle ear ehind the ear-drum.

The Operation.

The skin behind the ear is painted with tincture of iodine nd a light general anæsthetic given, preferably chloroform, hich ensures less bleeding. ½ per cent. phenolaine* (a local næsthetic) is injected subcutaneously, and an incision is ade close behind the pinna. When the periosteum is eached phenolaine is injected under it and also between he cartilaginous canal and the bony meatus. The peri-steum is incised and separated from the bone with a aspatory, all redundant periosteum being cut away. IcEwen's triangle is located, and a retractor inserted, so s to pull the pinna forward. All the vessels on the posterior ap are clamped, while those on the anterior are compressed y a small wad of cotton-wool under the retractor.

A hole is then bored over McEwen's triangle with a hand ouge 11 mm. in diameter. The boring is continued in a irection which cannot be previously defined, as it must llow the line of least resistance, skirting in front of the teral sinus. There is a thin dense wall of bone lining the nus, which can always be seen as a dark blue mark. inally, depending upon the anatomy of each case (and l are different), an occasional cell is reached about 10 mm. om the surface; though less frequently there are cells mm. from the surface. The 11 mm. gouge is used till a inness is noticed at the bottom of the boring. A 7 mm. gouge now used, and the boring, or rather filing or scraping ocess, is continued until the thin wall of the antrum, or tic of the middle ear, is reached and gently scraped away. he first opening to appear is probed to discover whether it only a cell or a larger cavity leading into the middle ear; e excavation is continued till a definite opening of about mm. diameter is produced. A strong probe with a short ght-angle bend is inserted and the thin wall between e antrum or middle ear (as the case may be) and the ring is broken away by pulling outwards. A fine probe, nt at an angle of 45° at the tip, is carefully passed at e bottom of the boring towards the middle line to ascertain the attic of the middle ear has been entered. Great care taken not to disturb the processus gracilis of the malleus. he total depth from the surface of the skull to the bottom the attic is 22 mm.

The posterior portion of the cartilaginous canal is now parated from the osseous canal, and the ridge of bone ween this canal and the boring is scraped away with the mm. gouge for about 5 mm. The cartilaginous canal is ided transversely at the level of the ridge and two gitudinal incisions are made so as to reflect a flap of the al outwards. A broad director is inserted through the ernal auditory meatus under the flap, and the incisions continued, till the external auditory meatus will admit tip of the little finger.

The flap is now sewn with catgut to the under surface of reflected skin, so as to keep the widened meatus patent, l stop bleeding.

Two suitable rubber tubes are now inserted from the ernal meatus to the bottom of the boring.

The incision at the back of the ear is closed with horse-, a small opening being left at the bottom for drainage. ear is smeared with carbolised (1 per cent.) vaseline a dressing applied behind it.

hammer is never used as the bone is extraordinarily able in density. In old-standing cases it is ivory-hard there are no cells, while the lateral sinus forms a bend ards the external auditory canal. The facial nerve runs risk, while the lateral sinus can always be seen. The a mater is occasionally seen when the bone is very dense; is when the cranial cavity comes lower down than usual, ll the space normally occupied by the mastoid cells.

After-treatment.

he tubes are syringed out and one is removed on the day; on the second day the remaining tube is removed the cavity plugged with narrow ribbon gauze. The e is removed twice a day and the cavity syringed out er with 1 in 4000 perchloride of mercury or with odide, or with a weak solution of hydrogen peroxide, or ochlorite.

y the end of a week the cavity discharges a good deal ucus. The orifice is kept patent with gauze plugging, which is renewed once or twice a day for three weeks. On each occasion that the plugging is removed the cavity is syringed out with a weak antiseptic. Special care should be taken to inspect the bottom of the boring with an auro-scope, so as to keep the foramen open which enters the middle ear; this is about 18 mm. from the surface. By the end of the third or fourth week mucous membrane lines the boring and joins with the skin of the external auditory canal. After a month or so the patency of the external opening is maintained by using a large lacrymal probe. The patient usually goes home at the end of the third or fourth week. A thin membrane, almost like tissue paper, often forms across the opening after some weeks and may require to be pierced every now and then if the hearing diminishes.

The result of the operation is to produce a new air passage to the middle ear. This incidentally opens the Eustachian tube, as the middle ear is now no longer a closed cavity, and so the patient can easily blow air through the Eustachian tube via the middle ear and out by the extreme auditory meatus. The middle ear is also drained, and the mucous membrane rendered healthy.

Clinical Records.

CASE 1.—Woman aged 42. One ear was absolutely deaf due to total removal of the ossicles, ear-drum, &c., seven years previously. The other ear became slowly deaf, till finally she could not hear any conversation unless she saw the lips moving. She could not hear a tuning-fork held in front of her ear, but could hear it for a short time when it was placed on the mastoid. As she is a school mistress her deafness was a calamity. I operated in 1922. Six months afterwards she found no improvement and attended a school for lip-reading, as she felt there was no hope. Personally I was hopeful, because she heard me call out her name when her back was turned to me. A year later the improvement was noticeable to her sister, but the patient herself would not admit it. Four years after operation the improvement was so marked that she answered numbers and single words spoken in a moderate voice in the dark and in the open air 12 yards away. She is not now noticeably deaf.

CASE 2.—Woman aged 29. Had steadily grown more deaf for six years, until finally she was too deaf for ordinary conversation, and never attempted to hear unless the speaker spoke close to her ear. In 1923 I operated on both her ears. In 1924 she reported very considerable improvement. In 1926 she wrote to say she was no longer deaf and was very happy, and was getting married on the strength of her restored hearing.

CASE 3.—Woman aged 68. She had given up all social functions, as she could only hear with a speaking-tube. In 1925 I operated on both her ears with a month's interval. Her improvement was so marked in six months that she was again able to take up the social duties her position entailed.

CASE 4.—A masseuse aged 50; operation 1922. She could not even hear a tuning-fork on the mastoid, nor a motor horn nor church bells. I operated on both ears with a week's interval. After three months she heard a tuning-fork on the mastoid and a motor horn blown close to the ear. She practised hearing every day through a cardboard cylinder and a laryngophone. In a year's time she was able to hear quite well with a powerful electrical instrument. In two years she was able to hear the organ in church and also the choir. Now, with the help of a simple aid, she can hear ordinary conversation, and can very easily carry on her occupation.

Results.

I have operated on more than 200 cases, from the ages of 4 to 70 years. The results have been variable, depending upon the period of the deafness. The improvement in the hearing of many patients who have been deaf for 30 years has been astonishing, and no case has ever been worse after the operation. In many the deafness has been arrested, while in the great majority the hearing has been greatly improved.

Patients should be inspected periodically, wax and debris removed from the external canal, and perhaps the thin membrane punctured. Dr. Bordley, of Baltimore, has injected an antiseptic fluid several times into the middle ear through the passage I had made in the case of one of my patients. She is an American lady of 64, and she has written to say that she has been much benefited by the treatment. In this direction there is still plenty of scope for

Martindale.

research. I look upon a period of one to two years after the operation as essential for estimating the result. Many patients find a great improvement after the first month if not sooner, but more generally it appears after six months.

The best results are obtained where deafness is due to blocking of the Eustachian tubes with indrawn ear-drums. One might term this condition "throat deafness," resulting from neglected tonsils and adenoids, with a narrowed nasopharynx and high palate. Such patients are frequently very deaf, almost stone-deaf, and they suffer from very distracting noises in the head. In four extreme cases the patients had almost lost their speech, as they could not hear their own voices. Many patients of this type have a typical deaf voice, a typical adenoid expression, and a difficulty in breathing through the nose. The improvement naturally depends on the length of time the deafness has been present.

Less favourable cases are those in which the Eustachian tubes are patent and the nasopharynx large. I have operated on many cases of otosclerosis; the mastoid portion of the temporal bone is very brittle and there are many large cells. These cases are not very favourable, but even some of them have been improved.

A CASE OF

SUPPURATING DERMOID OF THE CEREBELLUM.

BY J. TODESCO, M.D. FLORENCE, M.R.C.S. ENG., D.P.H.,

RESIDENT MEDICAL SUPERINTENDENT, BOROUGH HOSPITAL, CROYDON.

THE following case is of interest on account of the rarity of cerebral dermoids and because of the bacteriological findings in the blood and cerebro-spinal fluid.

The Clinical History.

A girl, aged 1 year 9 months, was admitted to the Borough Hospital on Jan. 29th, 1927, as a case of diphtheria, owing to redness of the throat with a croupy cough. She had been quite well and intelligent until one week before admission, when she appeared ill, vomited suddenly, screamed constantly, and complained of pain in her head and limbs; the parents noted some stiffness of her head and neck.

She was born with a small hairy cyst over the external occipital protuberance. When 6 months old she fell on the back of her head; after this the cyst grew larger and started discharging purulent matter. It was removed at the Croydon General Hospital on July 12th, 1926, but the wound kept discharging for one month.

Condition on Admission.—The child was fretful and restless, with occasional spasmodic cough. The throat was injected, but clean. Temp. 102° F., pulse 128. There were no signs in the chest, and no rigidity of head, neck, or limbs. During the night she was restless, with screaming attacks lasting for 20 minutes; she appeared to have pain in her head, but was quieter the following day. On Feb. 1st she was worse, with rigidity of the head and neck and some retraction. She strongly resented examination and screamed incessantly. Her pupils were equal, reacting sluggishly to light; reflexes present, no Babinski but double incontinence. On lumbar puncture 25 c.cm. of turbid fluid under pressure were withdrawn. After this she was quieter and slept for some hours and her temperature fell to normal. Next day she was better and the rigidity and head retraction had disappeared. On Feb. 4th she again became restless, screaming constantly; stiffness of neck and head retraction were marked, but limbs flaccid. Tâche cérébrale noted. A second lumbar puncture yielded 16 c.cm. of turbid fluid, not under pressure. On Feb. 9th she suddenly vomited, and this continued almost daily subsequently. The vomiting was not related to food. Subsequently her condition did not vary much. She was extremely irritable if approached, screaming at the slightest sound. When left alone she had crying attacks lasting for 20 minutes or longer, the cry resembling "cock-crowing" rather than a meningeal cry. The child did not appear to know anybody; she took her feeds eagerly, though occasionally there was dysphagia. The nervous symptoms were variable; on some days the head retraction and rigidity of neck and limbs was marked, with a fixed stare, the child being unable to turn herself in bed, and lying on her side with fingers clenched on palms and legs drawn up. At other times there was complete vascular relaxation throughout the disease, pupils were equal and reacting, reflexes present. There was incontinence of both rectum and bladder, and marked general wasting. About the middle of March the skin over the neck and chest turned almost black, and subsequently peeled in small flakes, leaving a clear skin below; this discoloration spread successively to abdomen, arms, and legs; concurrently there was marked growth of hair over the back of forearms and calves. After a few weeks the skin was normal.

On the morning of May 28th she collapsed, becoming cold, pale, and pulseless, with shallow respirations. She was soon revived with stimulants. During the following days she appeared weaker and drowsy, the spasms of crying were less frequent, but she was still very irritable and resented being touched. On the night of June 6th the child was very restless, screaming constantly, and she died suddenly at 1.10 A.M.

Temperature and Pulse.—Throughout the disease the child ran an irregular temperature which reached 102·6° F. at first and fell to normal by the end of the second week. After this it kept almost normal, or subnormal, till March 22nd, when it started to rise irregularly with variations of 3° in 24 hours. It was normal by April, became irregular on May 21st, with marked variations, until about a week before death, when it was subnormal. The pulse was rapid and weak, imperceptible at times, and became slow and irregular during the last fortnight.

Bacteriological Findings.—Lumbar puncture was performed six times between Feb. 1st and April 7th at periods when there was marked rigidity of head and neck. The quantity of cerebro-spinal fluid withdrawn varied between 25 c.cm. on the first occasion and only a few c.cm. on the last occasion. It was turbid and under pressure on Feb. 1st and 26th, but only slightly turbid and not under increased pressure at other times. It did not reduce Fehling's solution. Microscopically it showed excess of polymorphs and a Gram positive diplococcus, which was also cultured from the blood. It formed slightly raised white colonies on agar, tending to run together with crenation at margin. Mannite, lactose, insulin, and salicin were unchanged; gelatin was liquefied; milk turned slightly alkaline and glycerine slightly acid. It formed acid with glucose, maltose, and cane sugar. These results were confirmed by Prof. J. C. Ledingham.

Summary of Post-mortem Findings.

Brain.—The brain was œdematous and the ventricles distended with excess of cerebro-spinal fluid. It weighed 29 oz. There was no visible exudate on vertex or base, and membranes were not thickened.

Cerebellum.—A white cyst of the size of a hen's egg occupied the greater part of the right cerebellar hemisphere. On section it had smooth laminated wall, and a quantity of thick yellow pus was evacuated. It also contained a coil of brownish fine hairs. The cyst was not adherent either to the skull bones or the cerebral membranes. All the skull bones appeared normal. Except for slight congestion of the kidneys and spleen all the other organs appeared normal. The cyst wall was composed of fibrous tissue and hairs were present. There was some round-cell infiltration of the cerebellar abscess. The following cranial dermoids are on record:—

A man[1] 22 years old, who died at Fort Pitt, was found to have a congenital encysted tumour with semi-fluid content under the integuments covering the frontal sinus. The cyst contained oil globules and hairs.

A boy[2] 2½ years old who suffered from squint and convulsions of body and limbs following a fall off a chair later became comatose and died. He had a cyst of the dura mater on the posterior part of brain causing a depression in the occipital bone. The contents were composed of opaque white substance and purulent material, and in many places mixed with fine hairs collected together in a lock.

A girl[3] aged 7 had been suffering from increasing loss of power in lower extremities and had fallen violently on the back of her head two years before admission to Charing

Cross Hospital. Post mortem an abscess was found which had invaded the greater part of both lobes of cerebellum. It contained purulent material, was lined with a cheesy layer of sebaceous matter, and contained a tuft of hair rolled in a coil. The abscess was a suppurating dermoid of the cerebellum.

A boy [4] 4 years old, with a year's story of fits and paroxysmal attacks of headache and vomiting, was admitted to the Royal Free Hospital, dying there three months later. He was well during the greater part of the time, except that at intervals of two to three weeks he had attacks of severe frontal headache and vomiting lasting a few days. A bright yellow tumour was found in the orbital surface of the frontal lobe in front of the optic chiasma. It had a definite wall containing numerous hair follicles and active sebaceous glands.

A man,[5] 75 years old, who had been an epileptic and had been in an asylum for 38 years, had a tumour in the frontal lobe which contained fat and epithelial cells in the centre, while in its walls were skin, hair, sebaceous glands, cartilage, elastic tissue, and muscle.

Laumalogue [6] describes a cerebellar cyst the size of an orange containing a yellowish-white granular mass and many curled hairs. It was adherent to the occiput by a fibrous band which was lost in the bone.

Conclusion.

Dermoids of the brain are very rare; they occur at all ages and often suppurate. Trauma appears to be a factor in causing them to grow. They often give rise to headache, vomiting, fits, and convulsions, but not to paralysis of limbs. Progressive mental dullness and drowsiness ending in coma are common sequelæ.

In the case now recorded there was also extreme irritability to touch and sound, a constant peculiar cry resembling "cock-crowing" rather than a true meningeal cry, marked general body wasting and double incontinence. It is interesting to note the intermittent character of the rigidity of head and neck and stiffness of limbs; there was never any change in the reflexes nor were Kernig's sign or ocular paralysis present, which they probably would have been had the child been suffering from meningitis.

The micro-organism recovered from the blood and cerebro-spinal fluid was not one of those usually found in meningitis, as was confirmed bacteriologically, though the cerebro-spinal fluid was turbid and under pressure. It is difficult to account for the curious darkening of the skin followed by desquamation which developed during the third month of illness. The congenital cyst over the occiput which was removed six months before admission to the hospital was presumably a dermoid which, according to the history, started growing after a fall on the head. This may have caused the cerebellar dermoid to grow at the same time. The specimen of the brain from this case is now in the museum of the Royal College of Surgeons of England, Lincoln's Inn Fields.

I wish to thank Dr. H. P. Newsholme, medical officer of health for Croydon, for permission to publish this case; Prof. J. C. Ledingham for confirmation of the bacteriological findings; and Dr. H. W. Southgate for the pathological report.

A "ROYAUMONT BED" AT THE ROYAL FREE HOSPITAL.—Recently the French Ambassador presented the nameplate of a bed bearing this designation. The cost of its endowment, £1000, has been raised by the Scottish Women's Hospital Association of the "Royal Free," an organisation founded in 1921 to raise money for the endowment of beds in the obstetric and gynæcological unit. A secondary object was to commemorate by a permanent memorial the work of the Scottish women's hospitals during the war. This is the sixth bed which has been similarly endowed.

Clinical and Laboratory Notes.

THE VALUE OF SODIUM TETRAIODOPHENOLPHTHALEIN IN STEARIN CAPSULES AS AN INDICATOR OF PANCREATIC OBSTRUCTION.

BY SPENCER MORT, CH.M., M.D. GLASG., F.R.C.S., F.R.S. EDIN.,
LIEUT.-COLONEL, LATE R.A.M.C.; SURGICAL DIRECTOR, NORTH MIDDLESEX HOSPITAL, EDMONTON; LATE ASSISTANT PROFESSOR OF SURGERY, GLASGOW UNIVERSITY.

WORKERS at the North Middlesex Hospital have for some time pursued a series of investigations on the surgical diagnosis of affections in the region of the liver, using salts of sodium tetraiodophenolphthalein or sodium tetrabromophenolphthalein.

Technique.

The technique of administration of these drugs is well known. The stomach and intestines are emptied by a suitable purgative, and the salt is administered in the evening, 12 hours before the X ray photograph is taken,

Radiogram showing shadows cast by stearin capsules of sodium tetraiodophenolphthalein in the cæcum in a case of pancreatic obstruction. (Radiograph by Mr. H. C. Mayle, M.S.R.)

just before retiring to bed. The patient is asked to sleep, if possible, on the right side. In certain cases X ray plates are taken again about 16 hours after administration, when a clear picture of the size, condition, and situation of the gall-bladder is seen and stones may be very easily detected.

We give this preparation, usually the iodine salt, by the mouth in the form of powder, in doses of 40–60 grains, without any toxic effect, the dose varying with the body-weight of the patient. The preparation we use is made by Messrs. Duncan, Flockhart and Co., Edinburgh. We have also given the drug in tablet form (Martindale's gelatin-coated "slipules iodoray"). Messrs. Boots recently supplied a sample under the name "cholumbrin," which is a stearin-coated capsule containing 7½ grains of the active substance, which passes intact through the stomach and dissolves under the action of the pancreatic juice in the small intestine. This averts gastric irritation.

A lady, aged 69 years, was referred to me recently by Mr. James McClure for diagnosis and treatment. She was given 10 capsules, each containing half a gramme of cholumbrin, and at the appropriate time she was X rayed. The salt did not appear to be excreted by the gall, and the capsules were passed into the large intestine, as is seen in the figure, where a number are seen lodging in the cæcum; one has passed through the greater part of the intestine, and is about to enter the sigmoid.

The abdomen had been carefully examined, and a tumour detected on the right side. In addition, there was well-marked jaundice, obviously due to obstruction of the bile-ducts. The X ray plate, with intact capsules, was puzzling. The patient had taken only half a pint of fluid after the capsules. It might be

that there was not sufficient fluid in the stomach and intestines to dissolve the coating, but I felt sure that there must be some form of intestinal juice which would dissolve it, and came to the conclusion that the obstruction must be in the region of the ampulla of Vater, causing deficiency not only in bile flow, but also in the pancreatic juices, especially steapsin.

I operated on the patient on Oct. 10th, 1927, assisted by Mr. R. L. Galloway, and the anæsthetic —nitrous oxygen and oxygen—was given by Dr. F. P. de Caux, anæsthetist to this hospital. The record of operation was as follows :—

A transrectus incision was made on the right side above the umbilicus, and the peritoneum opened. Quite a large quantity of free bile-stained fluid escaped. The exploring hand revealed small, hard, carcinomatous areas scattered through the whole of the omentum. The liver was very large, but no actual involvement could be seen. The gall-bladder was hugely distended, and its whole surface was covered with small cancerous nodules. The hilum of the liver was filled with growth, and the retroperitoneal tissues in the region of the pancreas showed the same condition. A diagnosis was made of general carcinomatosis of the abdominal organs, with the origin in the head of the pancreas. The abdomen was closed in layers without drainage. The wound healed, and the stitches were removed on the tenth day ; the patient was well, and the colour of the skin rapidly improved. The jaundice probably passed away as the result of manual dislodgement of mucus during the operation. Patient discharged, much improved, in 21 days.

Remarks.

An old-fashioned rough-and-ready method of diagnosis in pancreatic obstruction was to give a dose of castor oil and watch the result to see if the oil passed through undigested. A refinement of this was to give wax-coated capsules of methylene-blue. If there were pancreatic obstruction the urine would be uncoloured ; but in the absence of obstruction the capsules would dissolve, and the methylene-blue would rapidly make its appearance in the urine. In this case the capsules were sim larly undissolved, denoting pancreatic obstruction, in association with the more obvious sign of biliary obstruction, but, fortunately, *the material is quite opaque to X rays, giving visible evidence.*

As I have not seen any record of this observation in the literature of abdominal surgery, I am desirous of bringing this matter to general attention.

A NOTE ON
BLOOD TRANSFUSION IN SYRIA,
WITH AN ANALYSIS OF 1149 BLOOD GROUPINGS.

BY E. H. R. ALTOUNYAN, *M.C.*, M.D. CAMB.,
ASSISTANT SURGEON, THE ALTOUNYAN HOSPITAL, ALEPPO.

THE adoption of blood transfusion as a routine measure in hospitals is still far from universal, but soon there will be no justification for the practice of surgery where facilities for transfusion do not exist. In the Near East the wide prevalence of severe secondary anæmia due to chronic malaria gives a further incentive to the use of transfusion.

In a recent series of 145 transfusions in the Altounyan Hospital, Geoffrey Keynes's method for citrated blood alone was used. Some such method must always be preferred for emergency work in general hospitals, reserving the possibly more efficient, and admittedly more difficult, use of non-citrated blood for the treatment of anæmia and other "medical" conditions. It is true that 50 per cent. of my series had well-marked rigors, but I have seen a severe reaction after the transfusion of 200 c.cm. of non-citrated blood with a Becart-Pauchet syringe, while no deleterious effect of citrate on the blood count was observed. A pint of citrated blood ready for instant infusion may permit the successful removal of a dangerously adherent spleen, which would otherwise be abandoned as inoperable. Hybrid methods, employing paraffined tubes with "just a little citrate" added, have little to recommend them.

Blood Transfusion Service.

Every patient on admission is grouped and the group is noted in a prominent place on his chart. He is then asked to name a friend as donor or, alternatively, to deposit £2 to provide for a professional should occasion arise. The practice of blood-letting once or twice a year at the village barber's still prevails in this country, but the popular imagination which accepts the homely sweep of a dirty razor seems dismayed at the surgeon's array of shining needles. In this series about 40 transfusions were provided by the patients' friends.

Professional donors are entirely drawn from Armenian refugees and all healthy men and women under 40 are accepted. Active syphilis is excluded by a Wassermann or Sigma reaction ; in 117 blood examinations of apparently healthy candidates, 12 per cent. were strongly positive. The largest quantity of blood withdrawn at one time was 650 c.cm. One girl, aged 20, gave 450 c.cm. twice in one week without serious disturbance to her health.

Table giving Analysis of 1149 Blood Groupings.

Race.	Group 1.	Group 2.	Group 3.	Group 4.
Arabs	32 (5%)	216 (37%)	129 (22%)	212 (36%)
Armenians ..	23 (5%)	230 (53%)	56 (13%)	129 (29%)
Jews	9 (7%)	46 (38%)	19 (16%)	48 (39%)
General population	64 (5·5%)	492 (43%)	204 (17·5%)	389 (34%)

The table gives the blood group percentages of the three races that form the principal components of the Syrian population. In this country the Jews and Armenians represent almost pure racial groups, with little admixture of foreign elements. Under the heading of Arab are included some Turks, Kurds, and a few Greeks, as well as the nomad and town-dwelling Arabs. It is interesting to note that there is an appreciable difference in the percentages of Groups 2 and 4 given by the Armenians, on the one hand, and the Arabs and Jews on the other.

Technique.

The methods and apparatus described in Keynes's book on "Blood Transfusion" (Oxford Medical Publications) have been used throughout. The most difficult part of the procedure and the most important, if a supply of donors is to be maintained, is the painless withdrawal of blood. The following technique is in use at this hospital :—

1. A sphygmomanometer is wrapped round the arm well above the elbow.
2. An intradermal wheal, 2 mm. in diameter, is made with 2 per cent. novocaine immediately over the selected vein.
3. A very fine hypodermic needle, mounted on an empty 2 c.cm. syringe, is introduced at one edge of the wheal, picking up but not piercing the anterior wall of the vein, and re-emerging through the wheal at its opposite edge. The syringe is then disconnected.
4. A vertical nick of 1 mm. is made with a sharp-pointed scalpel through the wheal immediately below the transfixing needle.
5. A Keynes's needle sterilised in paraffin is slowly introduced into the vein and the blood led off by a rubber tube into a Keynes's flask containing 2 g. of sodium citrate dissolved in 50 c.cm. of distilled water.

Blood Grouping.

Out of 1149 groupings performed during the last two years, three cases of abnormality have been noted.

1. Auto-hæmagglutination occurred twice. At room temperature the serum of the patient agglutinated his own red blood corpuscles. This did not occur if the slides were placed immediately in the incubator at 37° C. One was a boy, aged 16, suffering from splenic anæmia. After splenectomy, and coinciding with an improvement in his general health, his blood reacted normally. The other was a man of 30 suffering from profound secondary anæmia, due to hæmorrhoids, and early malignant disease of the rectum. Both patients were transfused without ill-effects.

2. A girl, aged 20, suffering from advanced pulmonary tuberculosis from which she died a year later, belonged apparently to Group 2. Her serum was tested against the red corpuscles of a donor of the same group, and marked agglutination was noted. The test was repeated on two different occasions with identical results. In all ten

different donors, some of them belonging to Group 4, were tried, and finally it was decided not to transfuse the patient.

A man with advanced pulmonary tuberculosis, and a woman suffering from advanced cirrhosis of the liver, with ascites and splenomegaly, also appeared to present the same abnormality, although they could not be investigated as fully as the first case.

This part of the work was carried out by Miss Setyan and Miss Meryack in the hospital laboratory. The actual grouping tests of every patient transfused were seen by the doctor responsible for the transfusion. As an additional safeguard the serum of each recipient was tested directly against the corpuscles of the donor. The observance of these two precautions may save much remorse. Universal donors were seldom used.

A CASE OF MASSIVE TUBERCULOSIS OF THE LIVER.

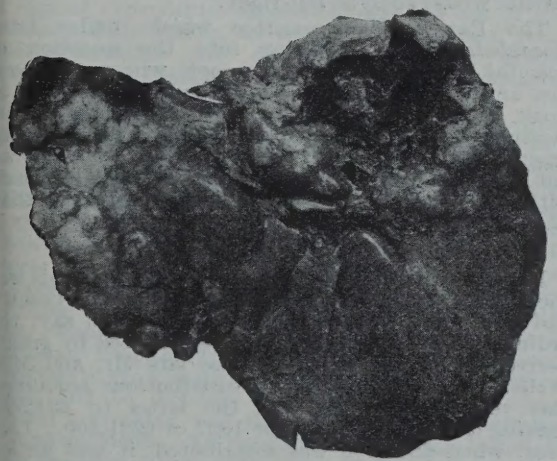
BY W. P. H. SHELDON, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET.

TUBERCULOSIS of the liver is generally seen in its miliary form when the liver becomes infected, in company with other viscera, as a terminal event to some tuberculous process elsewhere in the body. It is rare for chronic caseating tuberculosis to commence in the liver, and it is on this account, and also because of the difficulty of diagnosis while the disease was confined to the liver, that the following case is recorded.

The Case Related.

A boy, aged 11 years, was admitted to the Hospital for Sick Children under the care of Dr. Robert Hutchison in February, 1926, with a history that for six weeks he had suffered from sharp attacks of pain in the right hypochondrium. The pain occurred about 20 minutes after taking food, and often radiated up between the shoulder blades. During this period there had been three transient

FIG. 1.

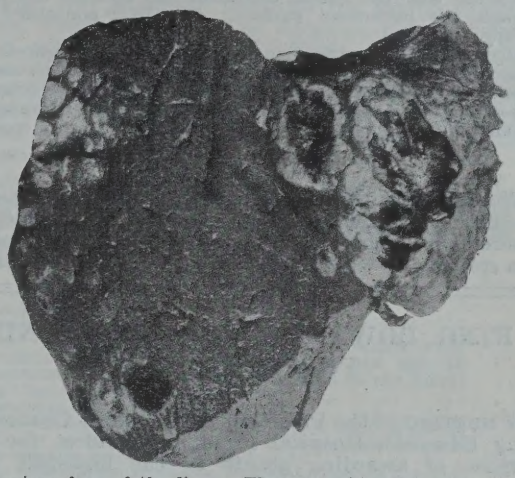


Posterior aspect of the liver, showing an abscess cavity in the right lobe and extensive involvement of the left lobe.

attacks of jaundice. A year previously the tonsils had been removed, otherwise the past history and family history were negative.

Condition on Admission.—The patient appeared delicate, with a clear complexion, free from any trace of jaundice. The lymphatic glands in the neck and in the right axilla were slightly enlarged. The heart and lungs were normal. There was some fullness in the epigastrium, the veins of the anterior abdominal wall were dilated, and the current in them flowed from below upwards. The liver was enlarged, but not tender, and extended two inches below the costal margin; the edge was grossly irregular and very firm, the surface felt coarsely nodular like a portal cirrhosis. The left lobe of the liver was well-defined, but the limits of the right lobe were ill-defined, especially deeply, towards the right renal region, where an indefinite mass could be palpated. The spleen was palpable half an inch below the costal margin, and felt quite smooth. There was no ascites nor œdema of the extremities. The urine was normal. The Wassermann reaction was negative; a blood count showed nothing abnormal beyond a slight secondary anæmia. The fragility of the red corpuscles was normal. A lævulose test (Dr. W. W. Payne) suggested a slight impairment of liver function, the figures being: blood-sugar before lævulose,

FIG. 2.



The cut surface of the liver. There is a big abscess cavity in the left lobe and another close to it. There is also a bile-stained cavity in the right lobe. Note the accumulation of small caseous areas in the right lobe just under the capsule.

0·084 per cent.; one hour after 35 g. lævulose, 0·110 per cent.; two hours after 35 g. lævulose, 0·107 per cent.

At first it was thought that the liver contained secondary deposits of malignant growth, the primary focus being in the region of the right suprarenal body; during the ensuing month, however, the clinical condition remained unchanged, and there was never any pyrexia; indeed, apart from the enlargement of the liver, the boy seemed to be in such good health that the diagnosis was altered to cirrhosis of the liver.

The patient was not seen again until October, 1926, when he complained that for two months his back had been aching. He was obviously thinner, but not jaundiced. The liver had not appreciably changed since February, but the spleen now reached the level of the umbilicus. There was still no ascites. The spine, in the mid-dorsal region, showed an early kyphosis, and the radiological report by Dr. Bertram Shires was that the body of the fifth thoracic vertebra was undergoing destruction and collapse with abscess formation.

The boy lived on for six months. During this time he had one attack of jaundice, which lasted a month and completely cleared up. The spinal deformity increased slightly, and signs of involvement of the right lung appeared. The liver and spleen remained unaltered. During the last two months there was a daily pyrexia up to about 101° F., and emaciation became profound. Eventually the symptoms of tuberculous meningitis appeared, and he died in April, 1927.

Post-mortem Examination.

The body only weighed 30 lb. The cranial contents showed the typical appearance of tuberculous meningitis. The bodies of the fourth, fifth, and sixth thoracic vertebræ were carious and had formed a large abscess, which was adherent to the adjacent pleura covering the upper lobe of the right lung. The lung in this part contained several small tuberculous cavities, and the rest of the right lung showed tuberculous broncho-pneumonia. The peritoneum was thickly studded with small cauliflower-like masses of caseous material; there was no ascites, nor were the intestines welded together into the conglomerate mass characteristic of advanced plastic tuberculous peritonitis. The spleen (weight 150 g.) was enlarged, and its capsule was covered with similar caseous tufts, but the spleen pulp was entirely free of tubercle formation. Both kidneys were enlarged (weight 120 g.), but contained no tubercles. The mucosa lining the stomach and intestines was normal; the mesenteric glands contained a few foci of miliary tuberculosis. The liver (weight 1250 g.) (Figs. 1 and 2) extended down to the umbilicus. Its surface was covered with caseous masses, while projecting from the liver substance through to the surface were many bosses of yellow tuberculous material. The left lobe was almost entirely occupied by a large abscess which was filled with a greenish-yellow liquid consisting of liquefied tuberculous pus, broken-down

liver substance, and bile. In this were suspended pieces of more solid caseous material. The walls of the abscess varied in colour from deep green to yellow, and were crossed by thick fibrous septa of supporting liver tissue. In the upper part of the right lobe of the liver was a similar abscess. In addition, the right lobe contained several smaller areas of solid yellow caseation, situated just under the capsule, suggesting that the causal organism had entered the liver through the peritoneal surface. The liver contained no miliary tubercles.

Microscopical examination confirmed the diagnosis of tuberculosis of the liver. In addition, one of the strands crossing the wall of the abscess in the right lobe proved, on section, to consist of tuberculous material and original supporting tissue of the liver around a patent blood-vessel.

Commentary.

The mode of infection of the liver in these cases is uncertain, but some writers have called the condition tuberculous cholangitis, holding the view that infection spreads by way of the bile-ducts. Others consider that the tubercle bacillus reaches the liver through the portal vein, and that the abscesses formed in the liver do not become bile-stained until rupture occurs into a bile-duct. Certainly in the case here recorded most of the smaller caseous areas showed no bile-staining. A third possible route of infection is by direct spread through the peritoneum into the liver substance; this route seems the most likely in the present case from the grouping of the younger caseous areas under the liver capsule.

Massive tuberculosis of the liver is a disease of long duration, and gives rise to no specific symptoms; even jaundice seems to be uncommon, owing to the small number of ducts usually involved, and until a secondary tuberculous process appears in some other part of the body the condition is likely to be mistaken for cirrhosis of the liver.

I wish to thank Dr. Hutchison for permission to publish this case.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the President and General Council of King Edward's Hospital Fund for London, for the purpose of awarding grants to the hospitals and convalescent homes for the present year, was held on Dec. 13th at St. James's Palace, the Prince of Wales being in the chair.

Remarks by the Prince of Wales.

The Prince of Wales read the following message from the King: "The King is very glad to hear that King Edward's Hospital Fund is increasing its distribution from £245,000 to £247,000 with the help of the League of Mercy, who are contributing £17,000, instead of £15,000. His Majesty offers his congratulations to all concerned, and earnestly trusts that the Fund will continue to make the same steady progress in the years to come." For the last two years, said His Royal Highness, the ordinary distribution had remained at £245,000. This year it had been increased to £247,000. The quarter of a million was being approached. Another £2000 had been advanced this year because the League of Mercy were giving £2000 more. Without this extra £2000, a distribution of £245,000 only would have been maintained. The British Charities' Association were again giving £15,000. Only one large donation had been given to the general fund—namely, £8000 from an anonymous friend. But legacies showed an increase of £10,000, and income from investments had risen by £3000. The capital fund continued to grow. The largest donation added to investments this year was Mr. H. W. Marshall's gift of £10,000 Conversion Stock. The legacy of £60,000 bequeathed to capital by the late Lord Iveagh had, of course, not yet been received. The total distribution for 1927 was, however, not £247,000, but £281,500. For grants were being made of £34,500 out of the legacies of the late Mr. and Mrs. Wells for special purposes, particularly schemes of extension and improvement. The distribution of these legacies had not yet quite finished; but they had already helped to provide more than 1300 additional beds, including 144 beds for accident cases, which were becoming a problem for all hospital people. The report of the Distribution Committee dealt with another aspect of this problem—the best way of providing immediate medical attendance on accidents and other emergencies at the outlying hospitals, many of which were developing out of cottage hospitals into general hospitals. Some of these had resident medical officers, some had not. The Distribution Committee had studied the visitors' reports; they had had a conference with the principal hospitals concerned; they had formed their own views on the subject; they had circulated them to the hospitals; and they now recommended that the Council should publish them. But they had laid down no rules; they would for the present content themselves in most cases with asking each hospital each year if it was satisfied that its own methods were adequate. thus combining the influence of a voluntary central body with the freedom and responsibility of the separate voluntary hospitals. The figures in the report showed that hospital expenditure continued to grow with the increase in the number of beds. Hospital income decreased a little during 1926, which was a year of exceptional difficulty. The hospitals, therefore, had a deficit, for the first time since 1922. It was not large—only a little more than 1 per cent. of their expenditure. It was chiefly due to a falling off in legacies, which had gone back to the level of five years ago. One thing was very encouraging. In spite of all the industrial depression, the patients' contributions continued to grow, working men and women—and much credit was due to them—were coming forward splendidly to do their share; and if everybody else did the same, the finances of the hospitals with deficits would soon be put right.

The Pay Beds Committee which, under Lord Hambledon, was inquiring into the question of hospital accommodation for people who were above the ordinary income limits, had been steadily at work, and expected to present its report to the annual meeting of the Fund in April or May. The pensions scheme for nurses and hospital officers was now all but complete; and would begin on Jan. 1st next, with 89 London hospitals, representing more than 12,000 beds.

The Financial Statement.

Lord Revelstoke (the hon. treasurer) said this was the fourth year in succession in which the Council had made two distributions; that was to say, the ordinary distribution, and that represented by grants derived from the legacies of the late Mr. and Mrs. Wells. The former of these distributions amounted this year to £247,000, and the latter to £34,500, making a combined total for 1927 of £281,500. Last year, when £245,000 was distributed, it was anticipated that it would be necessary to make use of the whole of the £9000 which had been added to the reserves in 1925. But, owing to the receipt before the end of the year of some unexpected contributions, they were enabled to limit the withdrawals to about half of this amount. At the November meeting this year the estimates showed that, with the aid of this unemployed balance, it would be possible to maintain the distribution at £245,000. With regard to the Wells legacies, £214,240 had been received on account, which amount covered the grants already made to hospitals and those recommended by the Distribution Committee. Lord Iveagh, who had been a very good friend to the Fund, had left £60,000 to be applied to capital account. This generous bequest, together with Mr. H. W. Marshall's gift of £10,000 3½ per cent. Conversion Stock, would substantially increase the capital fund, and would benefit the income derived therefrom.

League of Mercy.

Sir William Collins, in making the annual statement on behalf of the League of Mercy, said that the bulk of the receipts of the League were derived from collections which had to be gathered fresh every year. The amount was therefore apt to vary. This year they were able to make the King's Fund a grant of £17,000, £2000 above the amount handed over last year. They were distributing £13,283 to extra-metropolitan hospitals, including £5000 given by the British Charities Association for that particular purpose. From 1899, when it was established, until now, the League had given to the King's Fund £415,034, and to the extra-metropolitan hospitals £100,697; making a grand total, which the League had received and distributed to voluntary hospitals, of £515,731.

Grants to Hospitals and Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) presented the report of the committee on the distribution to hospitals (including recovery and convalescent branches) as follows, and moved the adoption of the list of grants. The report stated that the number of hospitals applying for grants is 141, as against 136 in 1926, new applications having been received from the Bermondsey Medical Mission, Croydon General Hospital, Harrow Hospital, Invalid Children's Aid Association, Heart Hospital at West Wickham, and St. Thomas's Cornwall Babies' Hostel. The accounts of all the participating hospitals taken together for the year 1926 showed that, while the total aggregate expenditure continued to increase, income showed a slight diminution, and there was, for the first time since 1922, a small aggregate deficit. The demands on the Committee have therefore continued to grow, and they were glad to have an increase, although a small one, in the amount available for distribution. The total grants recommended in aid of maintenance come to £211,450, as compared with £207,525 last year. The grants towards schemes of capital expenditure amount to £33,550 out of the ordinary distribution, as against £35,475 last year. The Committee are also recommending grants amounting to £34,500 out of the special distribution of the legacies of the late Mr. and Mrs. Wells. The total distribution to hospitals for the year is thus £279,500, besides £2000 to non-hospital convalescent homes. The Distribution Committee have been giving special attention not only to the provision of additional beds for accidents, but also to the question of the best method of securing prompt and efficient medical attendance, in cases of emergency, at hospitals which have no resident medical officer. This question has come before the Fund with increased importance for three reasons: first, the enlargement of the Fund's area, which has brought in several more small suburban hospitals; second, the tendency of such hospitals to grow in size, to take more serious operation cases, and to develop from cottage hospitals into general hospitals; and third, the increasing number of road accidents. Of the general or cottage hospitals with less than 70 available beds, 13 hospitals, ranging from 62 beds to 19, have resident medical officers. But 7 with from 40 to 55 beds are without a resident, as also are 14 with less than 37 beds. To some of these the Committee, while leaving the decision to the hospital, have expressed the view that the time has come for the appointment of a resident. The Distribution Committee have come to the conclusion that the most efficient system at such hospitals is one which includes: (*a*) the establishment of a rota securing the certain and most speedy attendance of one or more of the medical staff; (*b*) the appointment of one (or more) of the medical staff (either permanently or for a definite period) to pay daily visits to the hospital and make himself acquainted with the necessary facts concerning all the cases; (*c*) an arrangement whereby, in connexion with the rota, the member on duty undertakes to be available, or if unavoidably prevented, ensures that another member on the rota shall be available, and notifies the hospital to that effect. The hospital authorities thus always know beforehand who is the available member, and can communicate with him at once.

The Distribution Committee also consider that great importance attaches to the question of providing: (*d*) adequate facilities for taking notes on cases, whether medical or surgical, before deciding on a course of treatment. These conclusions have been notified to the hospitals without residents. Point (*d*) is even more important at these hospitals than at others, because the doctor who sees a patient under (*a*), (*b*) or (*c*) may not be the doctor under whose care he was originally admitted.

Lord Somerleyton (hon. secretary) presented the schedule containing the list of awards to hospitals (including recovery and convalescent branches) as follows:—

*List of Awards.**

	£
Acton Hospital	650
All Saints' Hospital	75
Babies' Hospital (Deptford Fund) (of which £250 towards rebuilding and extension on new site, in accordance with the scheme submitted to the Fund)	275
Baby Clinic Hospital (Kensington)	50
Beckenham Cottage Hospital	350
Belgrave Hospital for Children (of which £250 to deficit on new nurses' accommodation, in accordance with the scheme submitted to the Fund)	1,650
Bermondsey Medical Mission Hospital (towards erection of permanent wards, in accordance with the scheme submitted to the Fund)	50
Blackheath and Charlton Hospital	150
Bolingbroke Hospital (of which £500 towards extension, in accordance with the scheme submitted to the Fund)	2,250
Brentford Cottage Hospital (of which £500 towards rebuilding and extension on new site, in accordance with the scheme submitted to the Fund)	525
British Hospital for Mothers and Babies, Woolwich	550
Bromley Cottage Hospital	150
Carshalton and District Hospital	50
Central London Ophthalmic Hospital	500
Central London Throat, Nose and Ear Hospital	150
Charing Cross Hospital (of which £1,500 towards acquisition of adjoining building, and its adaptation as an extension of the hospital, in accordance with scheme to be submitted to the Fund)	3,500
Chelsea Hospital for Women (including Convalescent Home at St. Leonards)	900
Cheyne Hospital for Children (including Country Branch at St. Nicholas-at-Wade) (of which £100 to deficit on increased accommodation for artificial sunlight treatment and other improvements, in accordance with the scheme submitted to the Fund)	450
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park) (of which £250 towards new surgical block, in accordance with the scheme submitted to the Fund)	3,750
City of London Maternity Hospital	1,250
Clapham Maternity Hospital	300
Croydon General Hospital	500
Dreadnought Hospital (Seamen's) (including Albert Dock Hospital, Hospital for Tropical Diseases, Sanatorium at Liphook, and Convalescent Home at Cudham)	1,525
East End Mothers' Lying-in Home (of which £500 to deficit on acquisition of adjoining building and its adaptation for nurses' quarters, in accordance with the scheme submitted to the Fund)	1,200
East Ham Hospital (of which £750 towards rebuilding as general hospital, in accordance with the scheme submitted to the Fund)	925
East London Hospital for Children (including Convalescent Home at Bognor) (of which £500 to reduce debt)	3,525
Elizabeth Garrett Anderson Hospital (including Recovery Branch at Barnet) (of which £1,000 towards extension, in accordance with the scheme submitted to the Fund)	2,450
Eltham and Mottingham Cottage Hospital	25
Enfield War Memorial Hospital	300
Evelina Hospital	1,100
Finchley Memorial Hospital	300
Florence Nightingale Hospital for Gentlewomen	300
Forest Hospital, Buckhurst Hill	200
French Hospital	350
General Lying-in Hospital (of which £1,000 towards new nurses' home, in accordance with the scheme submitted to the Fund)	1,600
German Hospital	350
Golden-square Throat, Nose and Ear Hospital	200
Gordon Hospital for Fistula (of which £100 towards recent improvements)	150
Grosvenor Hospital for Women	500

* The Distribution Committee desire to draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

	£
Guy's Hospital (of which £1,000 to deficit on recent improvements)	11,500
Hampstead General and North-West London Hospital	2,750
Hanwell Cottage Hospital	50
Harrow Hospital (of which £500 to extension, in accordance with the scheme submitted to the Fund)	650
Hendon Cottage Hospital (of which £100 towards X ray room and sterilising room, in accordance with the scheme submitted to the Fund)	400
Hornsey Central Hospital	150
Hospital for Consumption, Brompton (including Sanatorium at Frimley) (of which £250 towards improvements, in accordance with the scheme submitted to the Fund)	1,100
Hospital for Epilepsy and Paralysis	2,000
Hospital for Sick Children	3,500
Hospital for Women (Soho-square)	1,000
Hospital of St. John and St. Elizabeth	750
Hostel of St. Luke	100
Ilford Emergency Hospital (of which £500 towards extension, in accordance with the scheme submitted to the Fund)	1,000
Infants Hospital	350
Invalid and Crippled Children's Society's Hospital (Canning Town)	500
Invalid Children's Aid Association Heart Hospital, West Wickham (of which £250 towards erection of ward pavilion, in accordance with the scheme submitted to the Fund)	350
Italian Hospital	300
Jewish Maternity Home	50
Kensington, Fulham, and Chelsea General Hospital	100
King Edward Memorial Hospital (Ealing) (of which £1,000 towards extension, in accordance with the scheme submitted to the Fund)	1,450
King Edward VII.'s Hospital for Officers	300
King's College Hospital	7,500
Kingston-upon-Thames Victoria Hospital	100
London Fever Hospital	600
London Homœopathic Hospital (of which £200 towards recent improvements)	1,950
London Hospital (including Recovery Branch at Reigate) (of which £1,000 towards improvements, in accordance with the scheme submitted to the Fund)	16,150
London Jewish Hospital	300
London Lock Hospital (of which £600 to maintenance of Harrow-road Hospital and £100 to maintenance of Dean-street Hospital, and £500 towards the building of an extension of the out-patient department at Dean-street, in accordance with the scheme submitted to the Fund)	1,200
London Temperance Hospital (of which £100 towards recent improvements)	2,100
Medical Mission of the Good Shepherd, Babies' Home (Hoxton)	25
Metropolitan Ear, Nose and Throat Hospital	25
Metropolitan Hospital (of which £1,000 towards new nurses' home, in accordance with the scheme submitted to the Fund)	5,000
Middlesex Hospital (including Convalescent Home at Clacton) (of which £1,500 towards reconstruction, in accordance with the plans submitted to the Fund)	8,825
Middlesex Hospital Cancer Charity	1,250
Mildmay Memorial Hospital	350
Mildmay Mission Hospital (of which £500 towards nurses' home and operating theatre, in accordance with the scheme submitted to the Fund)	1,400
Miller General Hospital for South-East London (including Convalescent Home at Bexhill) (of which £1,000 towards extension, in accordance with the scheme submitted to the Fund)	4,575
Mothers' Hospital of the Salvation Army (of which £200 to deficit on extension, in accordance with the scheme submitted to the Fund)	800
Mount Vernon Hospital (Fitzroy-square and Northwood)	1,250
National Hospital for Diseases of the Heart (of which £300 to deficit on extension of out-patient department, in accordance with the scheme submitted to the Fund)	600
National Hospital, Queen-square (including Convalescent Home at Finchley)	3,750
Nelson Hospital (South Wimbledon) (of which £250 towards provision of maternity block, in accordance with the scheme submitted to the Fund)	950
Northcourt Hospital and Home for Sick Children (Hampstead) (in consideration of the fact that curable cases are admitted)	100
North Islington Infant Welfare Wards (of which £50 towards additional nurses' accommodation, in accordance with the scheme submitted to the Fund)	100
Norwood and District Cottage Hospital	375
Ormond Maternity Home	—
Paddington Green Children's Hospital (including Convalescent Home at Slough)	1,000
Passmore Edwards Hospital for Wood Green, &c.	100
Phillips Memorial Homœopathic Hospital, Bromley	20
Plaistow Maternity Hospital	500
Poplar Hospital for Accidents (including Convalescent Home at Walton-on-the-Naze) (of which £250 to deficit on provision of children's ward, in accordance with the scheme submitted to the Fund)	475
Prince of Wales's General Hospital (including Convalescent Home at Nazeing) (of which £1,000 to reduce debt)	5,600
Princess Louise Kensington Hospital for Children (of which £500 towards building of new hospital, in accordance with the scheme submitted to the Fund)	525
Queen Charlotte's Maternity Hospital (of which £1,000 towards reconstruction and extension, in accordance with the scheme submitted to the Fund)	2,500
Queen Mary's Hospital for the East End (including Convalescent Home at Theydon Bois) (of which £1,000 towards new casualty block, in accordance with the scheme submitted to the Fund)	5,200
Queen's Hospital for Children (including Convalescent Home at Bexhill) (of which £250 to reduce debt)	4,050
Royal Dental Hospital of London	250
Royal Eye Hospital	750
Royal Free Hospital (of which £1,500 towards extension, in accordance with scheme to be submitted to the Fund)	6,500
Royal Hospital (Richmond) (of which £50 towards additional nurses' accommodation)	1,050
Royal London Ophthalmic Hospital (of which £750 towards provision of additional nurses' accommodation and wards, in accordance with the scheme submitted to the Fund)	3,250
Royal National Orthopædic Hospital (including Country Branch at Stanmore) (of which £500 to reduce debt and £1,000 towards extension of country branch, in accordance with the scheme submitted to the Fund)	4,500

Winifred House Invalid Children's Convalescent Hospital Home	25
Woodford Jubilee Hospital	75
Woolwich and Plumstead Cottage Hospital	25
Woolwich and District War Memorial Hospital (of which £315 towards preliminary expenses of maintenance)	390
Total	£245,000

Lady Hall having seconded, the motion was put and carried unanimously.

Distribution to Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) then presented the report of the Committee on the distribution to convalescent homes not attached to particular hospitals as follows, and moved the adoption of the grants.

The report stated: The President and General Council have this year fixed the sum available for distribution amongst convalescent homes not attached to any particular hospital in London at £2000, being the same amount as last year. The number of applications eligible for consideration amounted to 45, as compared with 44 last year.

Mr. Leonard Cohen (hon. secretary) presented the schedule containing the list of awards to convalescent homes not attached to particular hospitals as follows:—

	£
All Saints' Convalescent Hospital (Eastbourne) ..	200
All Saints' Convalescent Home (St. Leonards) ..	25
Baldwin Brown Convalescent Home (Herne Bay) ..	20
Beau Site Convalescent Home (Hastings)	25
Brentwood Convalescent Home for London Children (Brentwood)	25
Bushey and Bushey Heath Children's Convalescent Home (Bushey)	20
Catherine Marsh Convalescent Home (Worthing) ..	50
Children's Convalescent Home (Beaconsfield)	25
Children's Cottage Hospital (Cold Ash, Newbury) (in consideration of the fact that convalescent cases are admitted)	15
Children's Ophthalmic Convalescent Home (Mayfield)	10
Convalescent Home for Poor Children (St. Leonards) ..	100
Convalescent Police Seaside Home (Hove)	75
Friendly Societies' Convalescent Home (Herne Bay) ..	25
Home for Invalid Children (Brighton)	50
Invalid Children's Aid Association Homes—	
Brooklands Home (Worthing)	25
Clevedon Sanatorium (Broadstairs)	25
Convalescent Home for Children (Hawkenbury, Tunbridge Wells)	50
Countess Brownlow Home (nr. Berkhamsted) ..	25
Edgar Lee Home (Willesden)	25
Florence Emma Home (Dover)	25
Hamilton House (Seaford)	50
St. Michael's (Southbourne)	15
London and Ascot Priory Convalescent Home (Bracknell)	75
London and Brighton Female Convalescent Home (Brighton)	75
London Homœopathic Convalescent Home (Eastbourne)	25
Mental After-Care Association Homes (Fairlight) ..	150
Metropolitan Convalescent Institution (Bexhill, Broadstairs (Children) and Walton)	100
National Sunday School Union Convalescent Home (Clacton)	50
Pawling Home Hospital for Children (Barnet) (in consideration of the fact that convalescent cases are admitted)	10
Ranyard Mission Convalescent Home (St. Leonards) ..	50
St. Andrew's Convalescent Home (Folkestone) ..	75
St. Andrew's Convalescent Hospital (Clewer)	25
St. John's Home (Kemp Town, Brighton)	50
St. Luke's Home (Children) (Woodley, Reading) (in consideration of the fact that convalescent cases are admitted)	25
St. Mary's Convalescent Home (Birchington)	50
St. Mary's Home for Children (Broadstairs) (in consideration of the fact that convalescent cases are admitted)	75
St. Michael's Home for Men and Women (Westgate) ..	50
Seaside Convalescent Hospital (Seaford)	50
Suffolk Convalescent Home (Felixstowe)	50
Sunshine Convalescent Home for Children (Felpham, Bognor)	10
Surgical Home for Boys (Banstead) (in consideration of the fact that convalescent cases are admitted) ..	25
Tilford Convalescent Home for Children (Farnham) ..	50
Victoria Home for Invalid Children (Margate) (in consideration of the fact that convalescent cases are admitted)	25
Total	£2000

The motion, having been seconded by Sir Cuthbert Wallace, was then put and carried unanimously.

On the motion of Lord Mildmay, seconded by Mr. George Roberts, it was resolved that the cheques for the grants should be posted on Friday, Dec. 16th.

Wells' Legacies Distribution: List of Grants to December, 1927.

The Chairman of the Distribution Committee (Sir Cooper Perry) then presented the report of the Committee on the special distribution to hospitals in aid of extensions and improvements, out of the Wells' legacies to date, and moved the adoption of the list of grants.

This report stated: The total this year is £34,500 distributed to hospitals, besides £12,000 set aside, with the approval of the Council in May last, for grants in aid of pensions scheme for nurses and hospital officers. The amount allocated in the four years 1924 to 1927 is £224,250. The total amount of the legacies is not yet definitely known, but it is estimated that the balance as yet unallocated will amount to rather more than £20,000. The Committee hope to be in a position to submit a final list at the annual meeting of the Council in the spring. The grants during 1927 will assist in the provision of more than 180 additional beds, besides facilitating other forms of structural extensions and improvements. The total number of additional beds provided by the schemes to which Wells grants have been made during the four years is 1306. These include 144 beds reserved for accident cases.

Major H. A. Wernher (hon. secretary) presented the schedule containing the list of awards to hospitals (January to December, 1927) in aid of extensions and improvements, out of the Wells' legacies for the year as follows:—

British Hospital for Mothers and Babies, Woolwich.—£2000 towards second stage of new hospital; £1000 payable when the work is begun, and £1000 when the work is finished.

Central London Ophthalmic Hospital.—£500 to extension, increasing the number of beds from 40 to 52; payable when the work is begun, on condition that £6000 is raised by March 31st, 1927.

East Ham Hospital.—£2000 towards rebuilding as a general hospital, to be the last £2000 required to pay for the cost of the building; making, with £5000 granted in 1926, a total of £7000.

General Lying-in Hospital.—£1000 towards rebuilding of adjoining house as nurses' home and antenatal and postnatal departments; payable when the work is begun.

Harrow Hospital.—£500 towards extension, increasing the number of beds from 36 to 60, with accommodation for a resident medical officer; to be the last £500 required to render the extension free of debt.

Hospital for Epilepsy and Paralysis.—£500 towards extension, increasing the number of beds from 82 to 102; payable when the work is begun.

Invalid Children's Aid Association Heart Hospital, West Wickham.—£500 towards erection of open-air wards at new hospital, increasing the number of cots from 30 to 80.

Middlesex Hospital.—£10,000 as a third grant to reconstruction scheme; making, with £10,000 in July, 1925, and £10,000 in December, 1925, a total of £30,000.

Princess Louise Kensington Hospital for Children.—£1000 towards second stage of new hospital, increasing the number of cots from 15 to 55, payable when the work is begun.

Royal Free Hospital.—£5000 towards the scheme for the development of the hospital in celebration of its centenary; £2500 payable when the work is begun, and £2500 to be the last £2500 required to complete the first £100,000 raised by the appeal.

Royal Westminster Ophthalmic Hospital.—£2000 towards rebuilding on new site, increasing the number of beds from 42 to 85; £1000 payable at once, and £1000 to be the last £1000 required to render the new hospital free of debt.

St. Bartholomew's Hospital.—£7500 towards new surgical block, payable when the work is begun.

St. Mary's Hospital, Plaistow.—£2000 towards first stage of new out-patient department; £1000 payable when the work is begun, and £1000 to be the last £1000 to render the first stage free of debt.

Sir William H. Bennett having seconded, the motion was put and carried.

Pensions for Nurses and Hospital Officers: Present Position of the Scheme.

In the absence of Lord Donoughmore (Chairman of the Management Committee), the Vice-Chairman of the Committee (Lord Somerleyton) presented a report of the committee on the scheme of pensions for nurses and hospital officers, as follows:—

It stated that the Management Committee are informed that arrangements are being made to bring the scheme into operation on Jan. 1st under the title of "Federated Superannuation Scheme for Nurses and Hospital Officers (Contributory)." The scheme has so far been adopted by 89 hospitals in London, representing 12,176 beds out of a total of about 14,700. A large number of hospitals throughout the country are known to be awaiting particulars of the insurance companies' quotations, which are on the point of being issued by the Provisional Council. The details of the scheme in its present form differ only very slightly from those of the draft scheme as adopted by the hospitals represented at the Mansion House Conference in 1926.

His Royal Highness having briefly acknowledged a vote of thanks, the proceedings terminated.

On the same day His Royal Highness presided over the annual meeting of the League of Mercy, and read the following message from the King: "The Queen and I are gratified to know that the League of Mercy is able to render a satisfactory account of its work during the past year; and to learn that the contributions which the League has made to voluntary hospitals in London through King Edward's Hospital Fund and outside London by its own awards now exceed £500,000. In founding King Edward's Hospital Fund and the League of Mercy it was the aim and object of King Edward to maintain hospitals on the voluntary system, and we congratulate supporters of the League of Mercy on the successful results of their endeavours in this direction."

Reviews and Notices of Books.

GLYCOSURIA AND DIABETES.

Modern Methods in the Diagnosis and Treatment of Glycosuria and Diabetes. Fourth edition. By HUGH MACLEAN, M.D., D.Sc., F.R.C.P., Professor of Medicine, University of London, and Director of the Medical Clinic, St. Thomas's Hospital; Honorary Consulting Physician to the Ministry of Pensions; Consulting Chemical Pathologist to St. Thomas's Hospital. London: Constable and Co., Ltd. 1927. Pp. 212. 12*s.*

THE appearance of a fourth edition shows the demand which exists for books on the treatment of diabetes mellitus. No important changes have been made, but additional details about the value of insulin, as a result of the experience of the last four years, have been added. The dangers of insulin are described, together with the remedies which make them negligible. A word of warning is given about the treatment of patients who have symptoms of angina pectoris. The diet tables have been improved, but the reader must still be prepared to make simple calculations to ascertain how a food which contains carbohydrate may be substituted for any other food. A note on the dangers of so-called diabetic foods is timely, as harm is being done to patients who imagine that they are eating carbohydrate-free food. The observations on the results of insulin treatment show the range of improvement achieved in the condition of the patients. The statement that insulin of double strength has recently been put on the market by one firm requires amendment, for we believe that it was prepared by several firms as soon as the Medical Research Council agreed to its issue. It would seem that Prof. MacLean still uses Fehling's solution for sugar-testing, whereas other writers in this country, as well as in Canada and the United States, regard Benedict's qualitative solution as more accurate and easier for the patient to use.

The Diabetic Life. Its Control by Diet and Insulin. Third edition. By R. D. LAWRENCE, M.A., M.D., M.R.C.P. Lond., Chemical Pathologist and Lecturer in Chemical Pathology, King's College Hospital. London: J. and A. Churchill. 1927. Pp. 185. 8*s.* 6*d.*

IN a third edition of this book which has appeared within the year the author has not changed his practice in any essential degree, but there are a certain number of additions. An important chapter has been added on the new synthetic preparation synthalin, which can be taken by mouth; the results obtained were unsatisfactory. The diet tables, calculated on the 5-g. principle originally introduced by Leyton, are most valuable for the patient. Dr. Lawrence has been estimating the different amount of carbohydrate present in vegetables and fruits, and has introduced some of this work, although it is disappointing not to be able readily to identify the figures which he has altered. We would suggest the issue of pp. 114–167, which deal with diet and menus, in a separate cover for the use of wives or housekeepers who may be alarmed by the medical details which are necessary for the patient himself.

A Primer for Diabetic Patients. A Brief Outline of the Treatment of Diabetes with Diet and Insulin, including Directions and Charts for the Use of Physicians in Planning Diet Prescriptions. Third edition. By RUSSELL M. WILDER, M.D. Section on Nutrition, Division of Medicine, Mayo Clinic. London: W. B. Saunders Company. 1927. Pp. 134. 7*s.* 6*d.*

THIS primer which is mainly intended for the patient has been little altered in the third edition. It is written in simple language, and should be easily understood. The recipes for various dishes are good, but the diet tables involve more calculation than the majority of patients are able and willing to supply. Useful features of the book are the rules for the avoidance of damage to the feet and the help given in the treatment of complications, minor and major.

A TEXT-BOOK OF PRACTICAL THERAPEUTICS.

Twentieth edition. By HOBART AMORY HARE, B.Sc., M.D., LL.D., Professor of Therapeutics in the Jefferson Medical College, Philadelphia; Physician to the Jefferson College Hospital. London: Henry Kimpton. 1927. Pp. 1094. 36*s.*

IT is an ambitious conception to combine in a single volume a text-book of pharmacology, a handbook of general nursing and an index of treatment; yet such is the purpose of this book, and the fact that it has now reached its twentieth edition testifies to the success with which the author has carried out his project. The title is an accurate description of the contents which are essentially practical, and special methods of treatment, such as massage, which cannot be carried out by the practitioner himself, are not touched upon.

The book opens with a treatise on general therapeutic considerations, which contains in addition to a concise summary of the objects and limitations of medical treatment, directions for dosage and prescribing and tables of weights and measures. The next section is devoted to drugs, and the subject is approached essentially from the practical side so that, though theoretical considerations are by no means neglected, emphasis is laid on the uses of drugs, the methods of administration, and the forms in which they are put on the market. The list of drugs is thoroughly up to date, and includes a number of proprietary preparations of proven efficacy or whose value is still sub judice, in addition to official remedies.

Part III. is of particular value. In it are described those methods other than drugs that have a place in therapeutics, but which are usually left to the nurse to carry out, and too often are neglected by the student. The theory and indications for serum and vaccine therapy are well described, in addition to the uses and methods of applying such remedies as hot and cold packs, leeches, and poultices. There follows a short chapter on feeding the sick, with directions for making such articles as bran biscuits for diabetics, barley water, and peptonised milk. The remainder of the book takes the form of an index of treatment for those conditions that can be benefited by the therapeutic measures previously described. Thus abdominal emergencies are only dealt with from the point of view of expectant treatment, the indications for obtaining surgical aid being briefly outlined, and cancer, fractures, and similar purely surgical complaints are not mentioned at all. Although this section is compressed into little more than 300 pages, it is very comprehensive, and sufficiently detailed accounts are given of the various procedures to enable them to be carried out efficiently. Theorists might consider such headings as "Indigestion" and "Heart Disease" to be too vague a basis for accurate therapeutics, but adequate directions for differential diagnosis are given in the text, and the arrangement certainly makes for simplicity.

Works of this type do not claim to give full details of complex problems, such as the treatment of diabetes mellitus, and cannot replace larger and more specialised text-books. Their function is that of an encyclopædia which provides in the minimum of bulk the maximum of information on a wide range of subjects. The present volume fulfils this function admirably. It has been brought up to date, and its value as a book of reference is enhanced by two indices, one arranged according to remedies, and the other according to diseases.

MENTAL AND SCHOLASTIC TESTS.

By CYRIL BURT, M.A., D.Sc. Oxf., Psychologist, Education Officer's Department, London County Council. London: P. S. King and Son, Ltd. 1927. Pp. 432. 18*s*.

THE appearance of a third impression of Dr. Burt's monumental work is in itself an indication that it has met the requirements of many who had felt the need for a reliable scale of intelligence tests, standardised for the examination of children born and bred in England. The Binet scale had come from France, several revisions of it came from America, but until the first edition of this book was published there was no definitely English revision, and it had been carried out with so great care and ability that examiners, particularly of children suspected to be defective, have felt every confidence in using it.

In one respect Dr. Burt has departed from the policy of most revisers, and notably of Terman, whose Stanford revision has also found wide acceptance here, in that he has deliberately declined to add new tests to those of the Binet scales of 1908 and 1911. He admits that many tests introduced by Terman and others are valuable, but in favour of his own decision pleads in excuse the desirability of uniformity for comparative purposes. As, however, other revisers have so largely abandoned uniformity, this argument appears to lose its point, and to the examiner whose concern it is to diagnose as accurately as possible the mentality of a child, the plea of uniformity makes an appeal if it deprives him of the use of admittedly good tests, and at the same time compels him to use some admittedly worthless tests. Dr. Burt's criticism of Terman for retaining valueless tests renders him liable to an obvious retort. One has to admit, however, some point in his objection to patchwork revisions, and in his contention that what is required for real scientific work is a new scale, or series of scales, a task which would call for the coöperation of an army of workers. Dr. Burt is eminently qualified to be the generalissimo of such an army. His educational scales, which must have entailed great labour in their preliminary testing, have a much wider application than to the examination of the mentally defective. His analysis of the causes of backwardness in specific school subjects is illuminating. Of special value in diagnosis are his pictorial illustrations of the type of drawing of a man to be expected at different ages. These are based on an average of actual specimens and constitute an invaluable and unique age-scale of achievement in this direction.

The practical criterion adopted for certification of defectives for educational purposes, according to Dr. Burt, should be the amount of accommodation available in existing special schools. This comes with something of a shock to his fellow-workers, although such a criterion would doubtless be very comforting to local authorities whose provision of special schools was meagre, but who could claim that 100 per cent. of their defectives were in special schools. When the Board of Education puts upon authorities the duty of "ascertainment," its intention is that ascertainment should determine accommodation, and not that accommodation should determine ascertainment. Dr. Burt's concession to the practical here surely goes too far. His insistence on the distinction between defectives from the point of view of life and defectives who are only so for educational purposes is necessary, but too often forgotten, although to the school medical officer it is a commonplace. Dr. Burt estimates that one-third of the special school-children are of the latter type, and will grow up capable of managing their practical affairs without supervision. He merely suggests the possible impropriety of calling them defectives at all, but the necessity for their special education remains, whatever the label.

This book will remain a standard one on its subject until Dr. Burt's ideal scale is nearer fruition.

DIATHERMY.

Second edition. By ELKIN P. CUMBERBATCH, M.A., B.M. Oxf., D.M.R.E. Camb., M.R.C.P., Medical Officer in Charge, Electrical Department, St. Bartholomew's Hospital. London: William Heinemann (Medical Books), Ltd. 1927. Pp. 332. 21*s*.

DIATHERMY, both in its medical and surgical applications, is of increasing importance to the practitioner; he will welcome the new and revised edition of a book whose author is well known as an authority on the subject, and as one who has done much original work in connexion with it. Dr. Cumberbatch has a gift of lucid exposition of electrical matters, and it would scarcely seem possible to read the earlier section of this book without acquiring a clear understanding of the underlying electrical phenomena upon which diathermy depends. In a later section typical machines of British, German, French, American, and Dutch origin are fully described and illustrated, with an appendix in which the factors governing the choice of a diathermy generator are explained, and information as to maintenance is given. The following chapter deals with the distribution of the diathermy current in the tissues when it is passed through the body. This subject is discussed in the light of experiments made by Prof. Lloyd Hopwood, in which the current was made to traverse variously shaped solid masses of agar or gelatin dissolved in saline solution. Thermometers were thrust into the masses at suitable points to ascertain the rise of temperature, which is, of course, proportional to the current density. The section on "medical" diathermy opens with an account of the methods of application, types of electrodes used, and dosage, and sets out with great clearness the precautions which must be taken if burns are to be avoided. Details are given of the conditions in which medical diathermy is found to be of use, with notes of actual cases; of special interest is the account of the author's technique for diathermy of the urogenital tract in both sexes, with special reference to gonococcal infections. Dr. Cumberbatch's

successful pioneer work in this direction is well known. The final chapters of the book are devoted to high-frequency currents in surgery. As the author points out, there are several ways of coagulating, or even excising, malignant growths with the aid of heat generated within the tissues from the passage through them of a high-frequency current, but only one of these can strictly be called "diathermy." For this reason he prefers to use the general term "electrothermic methods of surgery."

The book is well produced and illustrated. It will be of value alike to the electrotherapeutist, the physician, and the surgeon. It can also be recommended to those studying for a diploma in radiology and electrology.

COMMON DISORDERS AND DISEASES OF CHILDHOOD.

Fifth edition. By G. F. STILL, M.D., F.R.C.P., Physician, King's College Hospital; Consulting Physician, Hospital for Sick Children, Great Ormond-street. London: Humphrey Milford, Oxford University Press. 1927. Pp. 1032. 30*s*.

THE thorough revision which this popular text-book underwent three years ago has left comparatively little room for material change in the present edition, but a number of chapters, such as those on infant feeding, nervous children, and nephritis, contain minor additions and alterations. Banana-pulp feeding is included among the therapeutic measures which the author has found useful in the treatment of marasmus. Dr. Still does not share the dislike of the use of lactose in infant feeding which has been evident in some recent publications; he regards lactose, in fact, as less laxative than any of the cane sugars. The principal addition to the book consists of three new chapters on vomiting, "pink disease," and cretinism. The first of these deals in some detail with the differential diagnosis and treatment of vomiting, stress being laid on the common occurrence of nervous factors in the ætiology of this symptom. An extremely interesting chapter on erythrœdema contains a description of its symptomatology, and a critical discussion on the exact nature of the disease. The author maintains an open mind on this question, but suggests as the most likely cause an intestinal toxæmia which produces a secondary peripheral neuritis.

This book is already a favourite both of students and practitioners, and its usefulness to them will be further increased by the additions which have been made to it.

VARICOSE VEINS.

Le traitement des varices. By Prof. J. A. SICARD and Dr. L. GAUGIER. Paris: Masson et Cie. 1927. Pp. 102. Fr.12.

THE injection treatment of varicose veins is now undergoing an extensive trial. In order that such a test should be a fair one, it is essential for the investigator to know the relevant work which has been done on the subject. In this little book he will find all the information he wants. The authors speak with the authority of pioneers, and their work has placed the sclerosing method of treatment upon a scientific and rational basis. This monograph is strongly recommended as a guide to any practitioner who proposes to adopt this method of treating varicose veins.

JOURNALS.

INDIAN JOURNAL OF MEDICAL RESEARCH. Vol. XIV., No. 2, October, 1927.—Two articles by J. A. Sinton contain further studies on malaria, with special reference to the action of "Peracrina 303," and intravenous injections of stovarsol, both of which methods proved unsatisfactory. The same writer with G. Covell, has found that the morphology of the buccal cavity of anophelines when macerated in potash constitutes a valuable aid to classification. H. D. Acton writes on porokeratoses and acquired angiomata or sarcoids; B. B. Bramachari on the prevalence of *Vibrio choleræ* in some of the endemic areas of Bengal; J. Cunningham contributes a note on the degeneration of vaccine lymph on passage through the same vaccinifer; T. A. Hughes and D. L. Shrivastava have investigated tropical cirrhosis of the liver, with special reference to the fragility of the red blood cells, carbohydrate intolerance in muscular dystrophy, and renal œdema. R. McCarrison publishes further work on the experimental prevention of stone in the bladder in rats. E. Muir writes on the effect of kala-azar in leprosy. A valuable and practical paper is the one by H. E. Shortt, Sribas Das, and Chirarji Lal on the finding of parasites in the peripheral blood of cases of kala-azar by direct microscopical examination.

Reports and Analytical Records.

VITAMIN CHOCOLATE.

(J. LYONS AND CO., LTD., CADBY HALL, KENSINGTON, W. 14.)

WE have received samples of Messrs. J. Lyons and Co., Ltd., vitamin chocolate and have submitted the claims of the manufacturers to investigation.

To test the vitamin A content, rats weighing from 40 g. to 50 g. were given a diet consisting of—

Caseinogen "vitamin-free"	15 g.
Dextrinised rice-starch	70 g.
Agar-agar	2 g.
Salt mixture (Steenbock's)	5 g.
Dried yeast	8 g.

The dry mixture was irradiated for half an hour under a quartz mercury-vapour lamp running at 2·5 ampères 130 volts. For this it was spread out in thin layers, about 100 g. over an area of 4 sq. ft. It was stirred and re-spread after a quarter of an hour's irradiation. By this process adequate quantities of vitamin D were generated in the ration. When rats which have become steady in weight on such a diet are given a substance containing vitamin A, their growth response is deferred until, presumably, the various disorders due to the deficiency are cleared up. To test the vitamin A content of the chocolate 14 rats were used in all. A comparison was made (*a*) with a sample of best English dairy butter and (*b*) with an average sample of cod-liver oil. For the former test a litter of nine rats together with one extra rat (not strictly comparable) were used. The chocolate and butter were tested in doses of 0·05 g., 0·1 g., and 0·2 g. respectively. The curve of growth of the rats at each level of feeding indicated that the chocolate was slightly richer in vitamin A than the sample of butter used. The comparison made with the cod-liver oil indicated that the chocolate had about one-fiftieth of the vitamin A activity of the oil.

To test the vitamin D content, rats weighing from 55 to 70 g. were given a diet consisting of—

Whole yellow corn ground	76 g.
Wheat gluten	20 g.
Calcium carbonate	3 g.
Sodium chloride	1 g.

Rats on this diet develop rickets in three to four weeks provided they have not made large reserves of vitamin D in their pre-experimental feeding. One litter of rats was used for the comparison between the chocolate and the same sample of butter as used in the vitamin A test. Doses of 0·1, 0·2, and 0·4 g. of each were used daily throughout a ten days' test period subsequent to the four weeks' preparatory period, and the degree of calcification induced indicated that the chocolate was slightly richer in vitamin D than the sample of butter with which it was compared. It must be understood, however, that butter cannot be considered a *rich* source of this factor, as even the best summer butters have only about one-eightieth the vitamin D activity of an average cod-liver oil.

THE LANCET.

LONDON: SATURDAY, DECEMBER 24, 1927.

CIVIL FLYING.

THE statement that within the past two and a half years a British company, Imperial Airways, has carried over 52,000 passengers without serious accident is testimony to the fact that civilian flying is now as safe as any other form of locomotion. This must, in part at least, be attributed to the careful medical selection and periodic re-examination of civilian passenger-carrying pilots. The conditions governing these examinations were originally laid down at the Peace Convention in 1919. Since that date they have been subject to systematic revision by the Medical Subcommittee of the International Commission for Air Navigation, and at their thirteenth session held in Rome last October the first general review of the methods of medical examination and the minimal standard of requirements was completed. These standards vary somewhat for what may perhaps with convenience be called the owner-flier and the air-pilot. In respect of the latter or public licence the regulations have now been amended to include the examination of women. Save in respect of peculiarities due to her sex, it will be noted that no particular allowance has been made for a lessened physical efficiency in women, except the admission of a lessened respiratory capacity. In certain quarters there has been a disposition to look upon this as an injustice to women, because it is felt that a woman of slight build cannot be expected to attain the same degree of bodily efficiency as a full-grown man. On this account small women may possibly, it is thought, be debarred from flying. Such, however, is not the case. What is overlooked is the fact that the small woman of the white race is not being examined under standards which apply only to men of her own race, but under such as apply to men of all the races of the world. The conditions, therefore, are such that every really healthy woman finds a reasonable chance of passing, provided she is endowed with the physical attributes which have been found in successful male pilots.

What are in fact the attributes of successful flying has been the subject of inquiry for some years, and is still being studied. The successful pilots of the past have set the standard of the present, and the successful pilots of the present will dictate the standards of fitness of the future pilots. Such a policy makes increasingly for safety in the air, since any special bodily condition be found associated with lack of success in flying, that condition is noted and the regulations modified accordingly. We speak of "condition" rather than "defect," since fitness for flying duties in respect of public transport and hands requires special qualities, the absence of which is not necessarily be termed defects in terms of everyday life. For example, the aeroplane pilot must possess a very high degree of accuracy of visual judgment if he is to fly, and particularly to land, an aeroplane successfully, although he could get on quite well in ordinary life with far less accurate visual perception. He must not be liable to "air-sickness," although such a liability would hamper him but little in everyday life on the ground. He must possess the general nervous stability which will keep him cool in emergency and will, even after long hours of flying or after flights in the rarefied air of high altitudes, leave him alert and controlled. He must be endowed with such respiratory and circulatory efficiency that he can resist the effects of the cold and rare air of altitudes. Above all, he must not suffer from any disability likely to cause sudden incapacity in the handling of aircraft. Nevertheless, the medical requirements are not really very severe. When the standards of efficiency are compared with those found in the average healthy young man or woman who has never flown it is found that they are such as can be passed with relative ease by those who have taken the trouble to keep fit and to lead a healthy life, provided they are blest with keenness of perception and aptitude for performance of coördinated limb movements. On this account, those who have all-round aptitude for sports and games, rather than especial prowess in one only, and have also the power of endurance, are the most likely (although not necessarily the only) subjects to become efficient pilots. In these days of women's athletic prowess there is little likelihood of many women aerial aspirants failing to pass the medical requirements laid down for them.

Each nation is at liberty to raise the minimal requirements laid down by the International Commission, and the requirements of physical efficiency of the male British pilots represent a high standard. A definite physical index is allotted as the result of each examination, so that at subsequent examinations an estimate can be formed as to whether there has been deterioration or otherwise as a result of the number of hours flown. The keeping of this index has proved of great service as a basis for the number of hours which can be flown without medical re-examination. Until recently pilots were to be re-examined every six months or after flying 250 hours. At the recent session of the International Commission it was decided to recommend, in addition to the six-monthly overhaul, re-examination when the pilot has flown 125 hours in any 30 consecutive days. The high standard of efficiency maintained by the British pilots is a matter for congratulation. The conditions for private flying are less stringent. Broadly speaking, any average first-class life can pass this examination provided he has a visual acuity for each eye of 6/9, without or with correction, an adequate degree of hearing, and suffers otherwise from no condition capable of causing a sudden disability. A recent provision, however, enables an owner-flier who is suffering from some slight defect, which precludes him from attaining the higher standard, to obtain the public licence after having given proof of his skill on his own machine.

CORONARY RESERVE IN MICE AND MEN.

ONE of the most surprising facts disclosed by recent work on the physiology of muscular exercise is the extent of the cardiac reserve and the enormous output which the heart is able to attain during severe exertion. This can be estimated from measurements of the oxygen intake. The oxygen consumption of an average man at rest is about 250 c.cm. per minute, and since a litre of blood will carry about 200 c.cm. of oxygen, from which the tissues extract about 35 per cent. when metabolism is basal, the estimated

output of the left ventricle at rest is about 4 litres per minute. During severe physical exertion such as rowing Prof. A. V. HILL [1] has shown that the oxygen intake may actually amount to 4·4 litres per minute. Under such conditions the dilatation of the capillary field will no doubt allow of a greatly increased coefficient of utilisation of oxygen (say 70 instead of the normal 35 per cent.). On the other hand, the circulation through the lungs is so rapid that the arterial blood has not time to get fully saturated with oxygen. Assuming that the arterial saturation is 18·5 instead of 20 volumes per cent., each litre of blood might give up 130 c.cm. of oxygen to the tissues. Hence an oxygen intake of 4·4 litres per minute means a circulation-rate of 34 litres per minute, and, taking into consideration the right ventricle as well as the left, the total cardiac output reaches the enormous figure of 68 litres per minute. From the ventricular output and the mean blood pressure it is possible to calculate the work performed by the heart. Allowing a 20 per cent. efficiency, an approximate estimate may be reached of the amount of oxygen which the heart muscle itself would require to perform this work. The result of this calculation shows that, during severe exercise, the heart muscle alone requires as much oxygen as is consumed by the whole body when at rest. So even in the first-class athlete the coronary circulation probably plays a very important part in limiting the amount of physical exertion which can be undertaken. In this connexion it is interesting to compare the conditions in the coronary circulation in man with that in other mammals. The mouse is the smallest living mammal, and this may perhaps be due to its having reached the limit in the matter of coronary flow. In warm-blooded animals the smaller the animal the higher is its basal metabolic rate, and consequently the greater its oxygen requirement. The heart-rate of a mouse is about 700 per minute, and as A. J. CLARK [2] has pointed out, a further increase of heart-rate is probably limited by the impossibility of the coronary circulation supplying the necessary oxygen. In spite of the fact that the mouse's heart is very large relatively to the size of its body, even at rest it is probably working near the limit of its oxygen supply. We are therefore led to conclude that the mouse's proud position as the smallest mammal is likely to remain unchallenged, since its would-be rivals must perish from coronary insufficiency.

SAFE CHILDBIRTH.

DAME JANET CAMPBELL'S report on the Protection of Motherhood [3] which has just appeared, supplements her earlier report on maternal mortality, published in 1924. The present report reviews the existing position of the problem in England and Wales, supplies the latest available statistics, discusses the vexed question of puerperal infection, and sets out in detail the essential provisions of a complete maternity service. It is notorious that the mother's risk in childbirth has not diminished in the way that the risk of the young child has diminished during recent years. The causes of maternal mortality are, it seems, less general and less easily influenced by educational methods than are the causes of infantile mortality. They are more individual and personal, more dependent upon the necessary clinical facilities being available at one particular moment, and hence they are less susceptible to influence by the methods which have contributed to the great reduction in the infant death-rate. This country with its mortality-rate from all puerperal causes of about 4 per 1000 live births occupies a middle position in a geographical sense. Rates are low in Italy, the Netherlands, Norway, and Sweden; high in Germany, Ireland, and Switzerland; and in Australia, where many districts are sparsely populated, the high death-rate is due chiefly to deaths from causes other than sepsis, the same being true of New Zealand. It was hoped that the improved training of midwives and the provision of maternity benefit would be followed by a substantial reduction in maternal mortality in this country, but this has not proved to be the case; nor has the infant mortality-rate in the first week of life shared in the remarkable decline of the total infant death-rate. Our knowledge of the origin and spread of puerperal infection is admittedly limited and inexact. Organised extension of what has hitherto been largely the work of individual investigators on isolated cases is an obvious desideratum, and Sir GEORGE NEWMAN would like to see every maternal death made the subject of competent and thorough medical scrutiny. Dame JANET CAMPBELL would strengthen and improve the maternity service by a scheme of domiciliary midwifery in which many normal deliveries and all maternity nursing would be performed by midwives, albeit always with the active support of the patient's own doctor who would be responsible for antenatal supervision, for the conduct of normal labour if so desired, for the treatment of any complication arising in the course of pregnancy or childbirth, and for the oversight of the lying-in period together with the care of the infant. Her report is not so much addressed to a medical audience as intended to educate public opinion, in order to persuade all concerned to combine in overcoming the practical difficulties of the problem.

It so happens that a remarkable object-lesson in carrying out the principles enunciated by Dame JANET CAMPBELL is available from one of the Dominions. A maternal mortality-rate of nil is recorded by the Victorian Bush Nursing Association, Australia, for the five years 1922–27. Dr. R. MARSHALL ALLAN, who was appointed by the Edward Wilson (Argus) Trust of the University of Melbourne as director of obstetrical research for two years, to inquire into the causes of maternal mortality and morbidity in Victoria, has just issued a report on the work of the Bush Nursing Association in which he admits that, though he had always valued the service of Bush nurses, he was both surprised and gratified at the magnificent record revealed by a study of the details. The number of cases dealt with in the five years under review was 2273, of whom 749 were delivered in hospital, 685 in the patient's home, attended by both doctor and nurse, and 839 in the home, attended by a nurse only. The proportion of cases coming under medical practitioners is steadily rising, this being mainly coincident with the establishment of Bush nursing hospitals; during the five years approximately two-thirds of the cases (63 per cent.) had the advantage of medical attention. Taking Victoria as a whole, the maternal death-rate averages about 5 per 1000 births, with a rate of 3·9 in the rural area of the State. This makes the absence of any maternal death the more remarkable, especially in view of the fact that on various occasions serious complications had to be treated by doctors in private houses, in addition to hospital cases. The population is composed entirely of white people, and woman's life in the Bush, though healthy, involves great hardships. Before the establishment of the Bush Nursing Association many families were 20, 30, or even 40 miles from medical help, and a woman expecting her confinement might have to travel eight hours or more over a rough road before she could obtain advice or help. The Bush nurses work in more than 50 different centres; they are picked women who take a special course of training in obstetrics and infant welfare. Their record shows that antenatal care was given by them to no less than 77 per cent. of the patients, and that they were quick to recognise any departures from the normal, and to report them to a doctor.

[1] Muscular Movement in Man. New York: McGraw Hill Book Co. 1927. 12*s*. 6*d*.
[2] Comparative Physiology of the Heart, Cambridge, 1927.

The whole of the factors making for safe childbirth were thus present—well-trained doctors and nurses working together as members of a team, efficient antenatal care, prompt removal to hospital of all cases showing any complication, and sufficient accommodation in well-staffed and well-equipped hospitals. The dwellers in the Bush are not only unusually fortunate in the maternity service provided for them, but unusually intelligent in availing themselves of it. Perhaps, too, there is less impatience among people accustomed to long distances and slow transport, so that the clamour for quick delivery, which Dr. ALLAN spoke of in his earlier report as a serious handicap to young obstetricians in the towns, is absent. As he says, the complete immunity from maternal deaths cannot continue indefinitely, but there is no reason why this enlightened community should not ensure permanently a mortality-rate well below what has almost come to be regarded as the inevitable minimum.

Annotations.

"Ne quid nimis."

"ASYLUM DYSENTERY."

THE high incidence of diarrhœal diseases in mental hospitals as compared with others has been attributed in varying proportion to the degenerate and dirty habits of mental patients, and to the failure of the medical and nursing staff to give them the attention which they would receive in the wards of a general hospital. Although clinical dysentery has been much reduced in recent years, many mental hospitals reporting only a few cases and some none at all, serological investigations have suggested that many more inmates harbour dysenteric bacilli than would be suspected from clinical observation alone. Since the pathologist penetrated to the wards of the asylum much work has been done on the detection of latent dysentery by means of agglutination tests. Mott and Durham [1] proved that the organism generally found in the fæces was a bacillus, though not usually one of a specific dysentery strain. According to the annual reports of the Birmingham Research Laboratories for 1925–27 no less than one-quarter of all inmates gave positive agglutinations with standard organisms, an unexpectedly large number agglutinating the food-poisoning group. Moreover, when the new admissions to the Birmingham mental hospitals were tested serologically it was found that, out of 34 admitted in 1926, no less than 23 per cent. gave positive results. The figure for all patients was 4·7 per cent. F. A. Pickworth, director of the Joint Board of Research for Mental Disease, Birmingham, has recently published a careful investigation into the agglutination of typhoid and dysentery organisms by the sera of mental patients.[2] He concludes, as a result of work on 2000 specimens of fæces and the serum of 100 patients whose fæces had shown aberrant organisms, that the bacilli of typhoid and dysenteric disease behave in a similar way to those of pneumonia; besides setting up acute disease they are frequently present as a chronic infection. The agglutination response is one out of possibly many effects of this chronic infection, but if it is taken as a constant indicator of the strength of the infection the results point to a very attractive hypothesis—namely, that a much larger proportion of the population than has hitherto been supposed is actually infected either with the specific organisms of dysenteric disease or with strains of very similar properties. "Some of these," suggests Dr. Pickworth, "may be attenuated or in symbiosis with other organisms, so that their detection by the usual methods is the exception rather than the rule, and in spite of infection and consequent marked demonstrable changes in the blood the actual disease process is so mild and transient as to be unnoticed or soon forgotten by the individual." If, as is reasonable to assume, a continuous access of these organisms to the blood stream lowers the titre by summation of negative phases, then many obscure chronic illnesses would be explained. "The immediate practical importance," he adds, "is that due values would be attached to any agglutination reaction as indicative of past infection with a possibly dangerous organism, quite apart from actual clinical disease, and these reactions should be regarded as seriously as an actual outbreak of a preventable epidemic disease." The high proportion of positive agglutination results in new admissions to mental hospitals certainly suggests some ætiological relationship between intestinal infection and mental disorder, and confirms the views expressed by Dr. William Hunter and others at the Edinburgh discussion last July.[3] At any rate it largely exonerates the institutions from the blame of negligently allowing the spread of dysenteric disease. Until, however, a widespread research has determined what proportion of the general population give agglutination reactions with these organisms, their rôle in the causation of mental disorder must remain unproven.

THE ANTIRACHITIC WAVE-LENGTH.

OUR knowledge of the wave-lengths of light concerned in the synthesis of vitamin D has been advanced a stage further by some researches of Dr. A. F. Hess and Dr. W. T. Anderson.[4] Hess and Weinstock had previously shown that the longest wave-length capable of protecting animals fed on a rachitic diet is in the neighbourhood of 3000 A.U. Following the discovery of the association of cholesterol with the antirachitic factor, the same observers were able to show that the line 3025, or possibly 3130 A.U., of the mercury arc spectrum was the longest wave-length to activate the cholesterol. The observation made by Rosenheim and Webster that ergosterol is the precursor of vitamin D led Hess and Anderson to investigate the region of the spectrum responsible for the activation of this pro-vitamin D. By the use of selective filters and improved apparatus, they have shown that cholesterol (presumably containing ergosterol) can be activated by a band of rays from 2650–2000 A.U., thus proving that rays shorter than the shortest U.-V. rays that ever penetrate our atmosphere are powerfully antirachitic. By further refinements three separate monochromatic rays were investigated, and it was found that 3130 showed slight antirachitic potency, while 3025 and 2800 A.U. of the same intensity possessed far greater antirachitic value. It appears therefore that the antirachitic rays of sunlight are restricted to the small band of rays at the extreme end of its spectrum. In view of the ease with which these rays are absorbed by smoke, dirt, and moisture, these results lend added weight to the plea for smoke reduction in crowded industrial areas where rickets is most commonly encountered.

PELLAGRA IN THE MISSISSIPPI FLOOD AREA.

PELLAGRA is always present in the region recently overflowed by the Mississippi floods—i.e., the States of Tennessee, Arkansas, Mississippi, and Louisiana. In a report [5] issued by the United States Public Health Service, J. Goldberger and E. Sydenstricker examine the conditions in which it normally occurs and the question of its increase in consequence of the floods. There is no doubt, they say, that the incidence of pellagra has very considerably increased, in the first three at any rate of the States named. Its

[3] THE LANCET, Sept. 17th, 1927, p. 606.
[4] Jour. Amer. Med. Assoc., Oct. 8th.
[5] Public Health Reports, U.S. Public Health Service, 1927, xlii., 2706.

frequent occurrence in normal years they attribute to the food habits and peculiar economic conditions which prevail in this cotton-growing area, and they show that the floods have simply operated to increase the economic pressure and to accentuate the pellagra-producing conditions. It is interesting to note that the wide occurrence of deficiency disease is almost always correlated with economic conditions when the basal diet is unsound. The basal diet of the Mississippi basin is often spoken of as the three M's ration—i.e., meat (salt pork), molasses, and meal (maize and some wheat meal), to which additions are made of dairy products, poultry, fresh vegetables, tinned meats, fish and vegetables, according to the means of the people. These means are unfortunately often small and irregular. The people are mostly small tenant farmers, growing a single crop, cotton, which brings in an income only at a certain time of the year. The cotton crop is always regarded as a speculative one, and may result in very different proceeds in different years. When, therefore, as in the last year or two, the cotton-growing industry is in a depressed condition, the people's means wherewith to buy supplementary foods are very small, and pellagra is bound to be on the increase. The bulk of the land being given up to the cotton crop, very few people have garden ground, nor is there much pasture for beasts, so that vegetables and dairy produce are scanty. This year's flood simply served to accentuate these conditions by destroying the cotton crop, drowning the beasts, and ruining such gardens as there were. Goldberger and Sydenstricker go on to make recommendations for the relief of pellagra in this emergency and for its prevention in more normal conditions. They point out that certain foodstuffs are particularly rich in the P.P. or pellagra-preventing factor. They say that when consuming only the basal diet already mentioned 40 to 50 per cent. of people will get pellagra in three to eight months, according to their previous nutritive condition. Lean meat, milk, or vegetables added to the diet will prevent this, and in particular any of the following as a daily addition: ½ lb. of lean beef, a full ½ lb. of dry cow peas, a quart of canned tomatoes, or 1 oz. of dried pure yeast. They therefore suggest that to deal with the increase of pellagra in the flood emergency local health officers should have a supply of dried killed yeast, canned tomatoes, canned salmon, or canned beef at their disposal to serve out to pellagra patients, who on adequate rations should recover in 6–12 weeks. For dealing with the chronic problem in the area they recommend diversification of agriculture to include cattle and dairy farming, the establishment of community dairies, and the cultivation of gardens, and allotments, as being the more easily modifiable of the conditions which are responsible for the wide occurrence of pellagra in this large area.

INFORMATION ABOUT THE TEETH.

SOME years ago the Dental Board decided to start a campaign against disease of the teeth, and has since spent a good deal of money in propaganda by films, lectures, and posters. In pursuance of its plan the Board has now published a small book[1] on the hygiene of the mouth and teeth, primarily intended for teachers, but also available for the general public. In preparing such a book the compilers undertake a difficult task, for it is hard to give an elementary yet faithful account of a technical subject, especially when the real intention is to prevent some disease. One must be dogmatic yet eschew controversy; on the other hand, it is unfair to give the subject a fallacious simplicity by assuming the truth of what are mere conjectures or by ignoring the evidence which seems to weaken the case presented. The anonymous authors of the Board's new book have succeeded admirably. Whilst skilfully avoiding the use of technical terms, they have not made the information too elementary, because the teacher whom it is specially hoped to reach may be regarded as an intelligent and educated class. Where a closely knit argument is necessary to tell the reader what are the factors concerned in caries, they have not hesitated to demand a certain amount of mental concentration and this is as it should be, for knowledge is best remembered if it is not acquired too easily. The anatomical description of the mouth and teeth is excellent and is somewhat detailed, as is also desirable, and there is a good chapter on defective development with pictures showing various forms of dental irregularity. No reader studying the photographs of individuals with what are aptly termed the rabbit, bulldog, and bird types of face can fail to realise the large part played by the teeth and jaws in shaping the features and the heavy handicap which irregularities may impose on the character and destiny of the person so afflicted. The problem of dental caries and its causation is dealt with fairly but perhaps a little too briefly; the authors seem to have skimmed over this subject warily in their laudable desire to avoid taking sides on the question whether the structure of the teeth or the diet is more important in the ætiology. Yet there are certain aspects which might have received a little more attention. It should have been made clear, for instance, that the acid which destroys the enamel is formed from carbohydrates, and that, so far as we know, the bacteria themselves cannot form lactic acid unless provided with a suitable pabulum. It is not without significance that certain carbohydrates, such as glucose are directly fermentable into lactic acid, and that for reasons of economy, glucose is often used in the manufacturing of cheap sweets. We should like to see more stress laid on the evil results of eating sticky carbohydrates, especially sweets, immediately before going to bed, when the muscular and glandular activities of the mouth are reduced to a minimum so that the lodgment of food against the teeth is facilitated. Since this book is intended as a handbook for teachers who will pass on their knowledge in suitable form to those under their influence, it is very desirable that facts like these which are closely bound up with our social habits should receive full attention. Naturally the authors were anxious to keep the book small, but the addition of ten pages or so on the causes and prevention of caries would have added much to its value without increasing its length unduly. These are minor criticisms, however, and it is a high tribute to the skill with which the book is written that there is so little that calls for adverse comment.

LEAD TETR-ETHYL.

THIS interesting compound, in which lead takes the place of the central carbon atom in tetr-ethyl methane, thus $Pb(C_2H_5)_4$, is one of many organo metallic compounds which, when mixed with petroleum spirit, reduce the speed of ignition and thereby decrease the liability to "knock" in internal combustion engines. It has been used for some time in the United States; in fact, its premature introduction led to many distressing cases of lead poisoning among those working with the substance itself. A question in Parliament, answered by the Home Secretary, made public the fact that spirit containing it is now sold in this country. The mixture is coloured to a pale reddish tint, so that it may be easily distinguishable. As it only contains about 0·07 per cent. of the tetr-ethyl it does not present the same danger as the undiluted compound. It should nevertheless, be used with caution, since lead may be absorbed from it into the system either through the skin or, more readily, through the lungs. Experiments on animals with lead tetr-ethyl have shown that there is considerable retention of lead, the excretion being appreciably less than the absorption. The tetr-ethyl compound parts with its lead very readily. A few tenths of a cubic centimetre of the commercial mixture heated with a smaller volume

hydrochloric acid in a sealed tube in a water bath r a few minutes will, when cooled, yield obvious ystals of lead chloride from which the characteristic actions of lead may be obtained. The hydrolysis ith the water of body fluids is doubtless slower, ut judging from the description of cases none the ss effective. This substance will no doubt be used rgely by the medical profession and by their car- ing patients, and if due care is taken very little rm will result. Physicians will, however, be well vised to remember that a new and somewhat sidious form of lead poisoning may occur in subjects ose vocations are not usually associated with this k.

LATE RESULTS OF ARTIFICIAL PNEUMOTHORAX.

TREATMENT by artificial pneumothorax has been vogue so long that a fairly accurate estimate of later effects can now be formed. The sceptic is t so likely to be convinced by the isolated case ated yesterday, however brilliant the result, as series of cases running into three figures and examined after a lapse of several years. In a ies of this kind recently described by Dr. H. Bjelke[1] patients had been given the treatment at his atorium during the past ten years. They were ssified according as their disease was of a chronic l productive or of an exudative character, and rs of their ultimate fate was obtained by corre- ndence. Of the 41 whose disease was exudative, belonged to the second and 36 to the third ban-Gerhardt stage of the disease. As many as were discharged from the sanatorium as improved, le four left it unchanged, and 14 in a worse condi- than on admission. Very few of these 41 patients e found to have survived; only five were still e, and several of these had but recently left the atorium. Thus the conclusion to be drawn from e figures is that when the disease is rapidly pro- sive and exudative the prospects of arresting it rtificial pneumothorax are none too good. Very rent is the outlook for the patient whose infec- is comparatively benign and chronic, for of uch patients in Dr. Bjelke's material as many 8 were found to be still alive. During the first years of the period under review most of the nts selected for pneumothorax suffered from the lative form of the disease, and when a five-year ey was made of their fate, it was found that of 8 treated up to 1922 no fewer than 29 had died, only ten were fit for work. But among the patients treated during the last five years, as y as 53 were found on inquiry to be fit for work. ut two of the 111 patients forming the whole s were sputum-positive before treatment, whereas ere discharged without tubercle bacilli in the m, or indeed any sputum at all. No case of mbolism marred these results.

CEREBRO-SPINAL FLUID PRESSURE.

ARIOUS methods have been used to measure ations in the pressure of the cerebro-spinal fluid e and during its withdrawal by lumbar puncture, hey all have their disadvantages, as Dr. E. S. re points out in a paper in the *Journal of the ican Medical Association* for Nov. 26th. The ary U-tube manometers and aneroids or other of spring-gauge manometers are difficult to se and of doubtful accuracy, especially at low ures. The simple upright tube from the lumbar ure needle, which shows the height to which pinal fluid will rise, is fairly reliable, except the pressure is very high. Dr. Kilgore thinks, ver, that accuracy is specially important in very cases, and to be correct the readings have to en before any fluid is withdrawn. An instrument designed for this purpose was described by Kausch in 1908, but it only permitted the removal, for purposes of examination, of a specimen of fluid mixed with saline, and this is a great disadvantage. In the apparatus which Dr. Kilgore has himself devised these difficulties are overcome. The lumbar puncture needle communicates laterally with one end of a miniature barrel which is divided into two halves by a rubber diaphragm, the other end of the barrel being attached to a U-tube. Before use the instrument is sterilised and filled with normal saline solution. After puncture the stilet is withdrawn, and if it has entered the subarachnoid space the pressure rises in the lumen of the needle, and the rubber diaphragm bulges towards the U-tube. The vertical limb of this tube is raised or lowered until the pressure on the two sides is equal, as shown by the return of the diaphragm to its normal position, and the height of the column of saline indicates the pressure. Cerebro-spinal fluid may then be removed by opening a stopcock on the other side of the needle, and by closing this stopcock the pressure can be measured from time to time in the same way. Dr. Kilgore says that until fluid is withdrawn the pressure may remain constant, or there may be a steady fall. In one case this fall seemed to be due to a drop in the blood pressure caused by puncture of the membranes. In a case of tabes dorsalis the pressure remained the same during the removal of 10 c.cm. of fluid. The great effect which removal of a small amount of fluid may have on the pressure was shown in the case of a patient with tuberculous meningitis. With the withdrawal of the first cubic centimetre the pressure fell from 400 to 320 mm., and it went on falling very rapidly as the next few cubic centimetres of fluid were removed. Readings taken with an instrument that could not show the pressure before the removal of fluid would in this case have given an error of 20–50 per cent. Dr. Kilgore has nothing to say of the clinical significance of pressure readings, but suggests that the types of pressure-volume curves occurring with spinal compression at various levels, or with coma of various kinds, may turn out to be useful in diagnosis.

[1] Tidsskrift for Den Norske Laegeforening, Nov. 1st.

A QUESTION OF NOMENCLATURE.

"SCIATICA is a rare and unusual disease," writes Dr. H. T. Patrick in a recent *Bulletin* of the Life Extension Institute of New York. On the other hand, Mr. Wilfred Harris says in his well-known book on Neuritis and Neuralgia, "Sciatica is a very common complaint." It is all a question of nomenclature. With the constant advance in our knowledge of the pathology of disease, the need of a standardised nomenclature becomes ever more pressing. Some years ago anatomists set an example by holding a conference to consider their own terminology, and although unanimity was not reached, there is at least an international terminology for any teacher to use if he cares to do so. Clinicians still wander at their own free will. Continental equivalents were left out of our "Nomenclature of Diseases" in its most recent edition, and the term "sciatica" appears only in the index of the Nomenclature with the remark, "*See* Diseases of Nerves." In the "International List" (of causes of death) the term appears under "Hysteria and Neuritis," subsection "Hysteria, Neuralgia." The two contradictory statements quoted above can only be reconciled by a recognition of the fact that the term sciatica is being used to designate two different conditions. Sciatica, the "common complaint," is pain in the region of distribution of the sciatic nerve, its components or branches. Sciatica, the "rare disease," is pain due to "an inflammation of the interstitial tissue of the sciatic nerve or its roots," as defined in "Modern Technique" (THE LANCET, 1926, i., 991). Even if the latter definition is accepted, it is doubtful if Dr. Patrick is correct in assuming that only ten cases out of every hundred of the "common complaint" are examples of the "rare disease," though Putti and other con-

tinental teachers incline to this view. There are several synonyms in use to describe pain arising from disease of the interstitial tissue of the sciatic nerve—e.g., neurofibrositis, interstitial neuritis, perineuritis, sciatic neuritis, essential, idiopathic, or true sciatica. Of these "sciatic neuritis" seems to be the most accurate, though "idiopathic sciatica" is being increasingly used. The fact that sciatic pain occurs in such diverse conditions makes a full examination necessary in every case, a point lately emphasised in our columns. It would surprise anyone who has not studied the matter closely to observe how often writers in medical journals are driven to begin their articles with a definition of what *they* think some particular word, phrase, or condition means, simply because there is no authoritative ruling to guide them. The need exists for a committee to define existing medical terms and to allocate new ones as occasions arise; such a committee might start by defining sciatica, eczema, cancer, and constipation.

THE ACTION OF SYNTHALIN.

ON Sept. 3rd we published a series of reports submitted to the Medical Research Council by various workers to whom synthalin had been issued for clinical trial. In doing so we pleaded for caution in view of the possible consequences of the introduction of the new remedy and drew attention to the somewhat disappointing results which had already been reported. What was said at the meeting of the Section of Therapeutics of the Royal Society of Medicine on Dec. 13th on the whole supported the belief we then expressed that the new substance has not substantiated the claims of its sponsors. Prof. H. H. Dale, relating the results of pharmacological experiments conducted in his laboratories, said that his co-workers have failed to produce any storage of glycogen in the livers of animals treated with synthalin, although they could easily demonstrate its reduction of sugar circulating in the blood. In an animal suffering from hypoglycæmia due to repeated administration of insulin, injection of adrenalin will always bring about immediate liberation of sugar from the glycogen stored in the tissues; but if the hypoglycæmia has been produced by synthalin this glycogenesis does not occur. In perfusion experiments on isolated limbs there was no deposition of glycogen in the muscles, although the blood-sugar disappeared under the action of synthalin, and Prof. Dale expressed the opinion that this fundamental difference in its action may well make synthalin a less valuable remedy than insulin in cases of diabetes. His impression was that synthalin caused a great fall in the blood-sugar only when the dose was large enough to inflict serious functional damage on the liver. Prof. Dale's experiments were admittedly made with toxic doses, because he wanted a recognisable effect; but Dr. P. J. Cammidge said that his own experiments with smaller quantities had given very similar results. Dr. George Graham, who spoke after Prof. Dale, gave interesting reports of 12 cases in which synthalin had been tried clinically with careful controls. In several of these its administration had enabled the physician to use a smaller dose of insulin, but complete replacement of the hypodermic preparation was only achieved in one case, and there were many failures and a number of toxic manifestations. Dr. R. D. Lawrence pointed out that synthalin could not be administered for long periods, and doubted whether the remedy had added anything important to the routine treatment of diabetes. Whether it is true that its employment is on the decline in Germany we are unable to say, but it seems clear that at present its use is laborious and its benefits often absent or doubtful. Prof. Dale's experiments go a long way towards explaining this disappointment, for they show that the mechanism by which synthalin reduces blood-sugar is very different from the true replacement-therapy by which insulin does its work.

Modern Technique in Treatmen

PREVENTIVE TREATMENT OF DIGESTI TROUBLES IN YOUNG CHILDREN.

THE most satisfactory means of preventing digest troubles in later life is to ensure the development a robust and well-disciplined alimentary syst during the period of its most active evolution—t is to say, during the first and second years of life.

Natural feeding, if properly conducted, ensures normal development of the digestive tract during most important period of all—namely, during first nine months of life—and artificial feeding substituted for it, should aim at producing sim results by means of a milk diet modified as accurat as possible to the standard of breast milk. moment that this milk diet, whether breast milk artificial, is relinquished for the mixed food wh is indicated at or about the time that the first te are cut, new difficulties and dangers immediat present themselves. Heretofore the infant presumably had no form of carbohydrate food ot than sugar (lactose, maltose, or sucrose). Now he to learn how to convert starch into sugar for him —a most necessary accomplishment, since starch some form or other will in future be the main art of his diet. He has to learn how to masticate s forms of food and to tolerate roughage or ballast fi vegetable fibre, in order that he may be provided v a solid basis for his stools.

It must be remembered that during the milk the physiological basis of the child's motions is s —insoluble soap—consisting mainly of stearate calcium; hence the necessity for a generous allowa of fat in the food at this period. With the substitu of a mixed diet for the milk the same amount of is not required, but ample provision must be made ballast of another kind. The milk diet ensures t the child receives at least some representation every one of the elements required for growth maintenance. There is no guarantee whatsoever t on a mixed diet all these elements will be provid indeed, it may be taken for granted that a large num of them will fall short of the physiological requ ment. The chief offenders in this respect are min elements, vitamins, and cellulose or roughage.

About forty different elements or proxim principles are required to complete the physiolo dietary of the child. Hence it is obvious that ur the food programme is thought out very carefully consists mainly of milk, many omissions or defect balance may occur and mar its physiological rectit One of the chief necessities in changing from the to the mixed diet is to introduce every innova very gradually.

Accompanying is a series of tables suitable different ages between 6 and 18 months, which I h drawn up in order to assist those who would fin irksome to arrange one themselves.

These tables, with or without modifications, ei by myself or others, have already been publi elsewhere, but are not for the most part e accessible.

At all periods of life included in this survey need for accessory food factors (vitamins, mi elements and extractives) should be kept constant view, and though some provision is made for the the combination of foods suggested in the acc panying tables, it is wise to ensure the inclusio a full complement of them from independent sou

The younger the child the greater the need for t essential imponderabilia of diet. It is often tho unnecessary to supply infants under three mont age with orange juice or other antiscorbutic. T

DIET TABLES—6–18 MONTHS.

(6 to 7 Months.)

6 A.M.	10 A.M.	Dinner, 2 P.M.	6 P.M.	10 P.M.
Breast or M.M., 6 to 7 oz.	Breast or M.M., 6 to 7 oz. Crust, butter, a trace.	Breast or M.M., 6 to 7 oz. Broth, 2 oz., *or* red gravy, ½–1 oz., given alone or with feed.	Breast or M.M., 6 to 7 oz. Crust, butter, a trace.	Breast or M.M., 6 to 7 oz.

(8 Months.)

reast or M.M., 7 to 8 oz.*	Breast or M.M., 7 to 8 oz.* Crust or rusk, ½ oz.; butter, ½ oz.; yolk of egg, ¼ oz., in feed or lightly boiled.	Strained veg. broth, 4 oz., *or* red gravy, ½ oz.; crust or twice-baked bread, ½ oz.; butter, ½ oz.; milk, 4 oz., alone *or* given with broth.	Breast, 7 to 8 oz., and crust, ½ oz., or M.M., 7 to 8 oz. with groats or baked flour, ½ oz., *or* crumb, ½ oz.	Breast or M.M., 7 to 8 oz.*

(10 Months.)

6 A.M.	8 A.M.	12 noon.	4 P.M.	8 P.M.
range juice, ½ oz.; sugar, ½ oz., with water.	Milk, 5–6 oz.; sugar, ½ oz.; toast or crust, 1 oz.; butter, dripping, or bacon fat, ½ oz.	Gravy, 1 oz., *or* broth, 4 oz.; potatoes, ½ oz.; veg. marrow, cauliflower, or other veg., ½ oz. Alternative meal: Fish pudding, 2 oz.; bread, ½ oz.; milk, 5–6 oz. sugar, ½ oz.	Milk, 5–6 oz.; sugar, ½ oz.; bread or crust, 1 oz.; butter, ½ oz.; stewed apples, 1 oz., *or* jam, ½ oz.	Milk, 5–6 oz.; sugar, ½ oz.

1 Year Old.

Breakfast.	Dinner.	Tea.	Supper.
lk, 6–8 oz.; sugar, ½ oz. ead, toast, rusk } Singly or combined 1–1½ oz. tter, dripping, bacon fat, &c. } Singly or combined, ½ oz. m (without seeds, pips or skins). lly, treacle, honey: ½–½ oz.	Fish, 1 oz., stewed in milk (2 oz.), *or* egg, 1 oz., *or* tripe stewed in milk, ½ oz. (milk, 2 oz.); potato, 1–2 oz., mashed with ½ oz. fat. Veg.: cauliflower, veg. marrow, Jerusalem artichoke, turnip, or Brussels sprouts, 1 oz. Milk pudding, 2 oz., or custard, baked or boiled. Stewed prunes or baked apple, 1 oz.; bread, 1 oz. Water to drink.	Milk, 6–8 oz.; sugar, ½ oz. Bread, toast, rusk, plain } Singly or combined, 1–1½ oz. Madeira cake,† oatmeal biscuits. } Butter, ½ oz.; jelly or jam without seeds, pips, or skins, ½–½ oz.	Bone and veg. broth, 3–4 oz. *or* milk, 6 oz.

(18 Months.)

lk, 8 oz.; sugar, ½ oz.; cocoa, z. Bread, toast, or rusk, 1½ oz. tter, dripping, bacon fat, ½ oz. n, jelly, treacle, honey, ½ oz. itercress or lettuce in season.	Fish, steamed, 1½ oz. (and served with white sauce); Potatoes, steamed and mashed with butter (½ oz.), 1½ oz.; carrots, turnips, boiled spanish onions, or soft. veg., 1½ oz. Sponge pudding, 2 oz. or sponge cake. Stewed prunes, dates, apples, apricots, well stewed and skins removed, 1½ oz. Bread, 1 oz. Water to drink.	Milk, 8 oz.; sugar, ½ oz. Bread, toast, rusk, sponge, or Madeira cake, oatmeal biscuits. } 1½ oz. Butter or marg., ½ oz. Jelly, jam, or treacle, ½ oz.	None. A hot drink if necessary.

M.M. = milk mixture. * Some of the water may be omitted. † Home-made.

9 months the diet is the same, except that dinner must be rather larger, and a few teaspoonfuls of stewed vegetable or baked apple pulp added.

not be a greater mistake, and the same applies to other accessory food factors. It is comparatively y to supply the latter from ordinary domestic ources, without having recourse to special prepara- ns, but many of these are now offered in concen- ted and convenient form by well-known drug- ists.

Vegetable and bone broth prepared according to own formula from chopped bone well boiled down h vinegar for many hours in order to decalcify it, h an addition of green vegetables which are only led for a short time, and liver, kidney, and other ernal organs, together with marmite, provide in ly concentrated form a valuable ensemble of most the required accessory factors; it can be given to nts and children of all ages.

Many commercial preparations such as roboleine, mar, vitaminose, virol, brestol, jecomalt, and iated malt, are all good and reliable preparations mixed vitamins. Vitamins A, C, and D are well resented in small leafed green vegetables, such as nach and brussels sprouts. Marmite is a concen- ed preparation of water-soluble D, and so are other st preparations, of which there are several on the rket. Ostelin is a reliable and concentrated paration containing the antirachitic factor. Mineral elements in physiological balance can be obtained by using a preparation which is now prepared. for me by Parke Davis, known as "nutritive salts."

ERIC PRITCHARD, M.D. Oxf., F.R.C.P. Lond.,
Medical Director of Infants Hospital, Vincent-square.

PRINCE ARTHUR OF CONNAUGHT ON THE TEACHING HOSPITALS.—Speaking last week at a meeting of the court of governors of Middlesex Hospital, of which he is chairman, Prince Arthur of Connaught expressed his belief that the public at large have not yet grasped the fact that the great voluntary hospitals have unostentatiously assumed responsibility for medical education and the advancement of medical science, and therefore do not appreciate the corresponding enlargement of their duty towards those institutions.

SMALL-POX HOSPITAL AT GRAVESEND.—Sir W. H. Thomas, chairman of the Port of London Sanitary Committee of the Corporation, last week opened a new building attached to, and a short distance removed from, the Port Sanitary Hospital at Gravesend. The building, which will be set aside for cases of small-pox occurring among the passengers and crews of ships arriving in the Thames, consists of two wards of four beds each with the necessary adjuncts.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1926 statistics of four English and two Scottish counties :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality from childbirth.
Kent (1,120,600)	16·2	11·0	0·85	1·42	1·5	1·6	6·0	55	3·6
Staffordshire (726,500)	19·9	10·9	0·87	1·08	2·0	1·4	8·2	72	4·4
Cambridgeshire (128,470)	15·2	11·8	0·86	1·75	1·5	1·7	1·0	53	3·6
Rutlandshire (18,020)	16·5	12·8	0·61	1·55	1·8*	1·3	3·3	63	6·6
Dunbarton † (54,227)	18·9	11·4	0·94	1·62	1·7	1·3	6·8	62	3·9
Dumfries† (46,108)	21·6	12·7	1·06	1·28	1·4	1·9	8·0	72	6·0

* Bronchitis and pneumonia only. † The figures refer to the county landward.

Kent.

Dr. Alfred Greenwood reports that the death-rates from both pulmonary and other forms of tuberculosis were the lowest ever recorded in the county. For the dispensary system the county is divided into eight districts and each of the eight tuberculosis officers is available for consultation at the request of the medical attendant. The county health nurses carry out health visiting and school nursing as well as the visitation of cases of tuberculosis, and it is estimated that the time devoted to the last-named work is equivalent to that of 8½ whole-time tuberculosis nurses. Institutional accommodation has been increased and there were 480 beds in use at the end of the year. The 1390 patients who received residential treatment included 69 ex-Service men, who were admitted to training colonies. The average duration of treatment for patients suffering from pulmonary tuberculosis was 158 days for males and 156 days for females. For non-pulmonary tuberculosis the duration of in-patient treatment was 330 days for males and 260 days for females. There has been great pressure on the non-pulmonary tuberculosis beds for which there is always a considerable waiting-list. Under the orthopædic scheme, which came into operation early in 1927, 48 beds are reserved for children suffering from bone and joint tuberculosis at the Alexandra Hospital, Swanley. Arrangements are made with various hospitals throughout the county and in London for X ray examinations to assist diagnosis, and 77 such were made during the year. Twenty-three patients received artificial pneumothorax treatment during the year, and Dr. F. J. Pierce (the medical superintendent of Lenham Sanatorium) reports that this treatment has proved most satisfactory, that several cases attend as out-patients, and that in the coming year their numbers will be considerably increased. Surgical appliances of various kinds are provided by the council free of charge when necessary. The 92 open-air shelters were loaned out to 129 patients during the year. The county dispensing station supplied a large amount of prescriptions, dressings, &c., to the sanatoriums and dispensaries.

The maternal mortality from childbirth was just equal to the average for the last 19 years. Efforts continue to be made to provide an efficient midwifery service, either by grants to nursing associations or by placing subsidised midwives with a guarantee minimum income of £100 in districts where there is not a livelihood for a midwife. The practising mid wives, numbering 342 (317 trained) attended betwee them 10,090 births and summoned medical help o 1642 occasions. A post-certificate course for midwive was held at Maidstone from Oct. 4th to 8th. Te lectures were delivered by specialists of various kind The attendance was better than last year, and 19 midwives attended part or all of the course. D Greenwood reports, after personal inspection maternity homes which have applied for registratio that most of them reach a high standard of equipmen Out of 128 homes inspected 111 have been registere and 17 hospitals and homes have been exempted fro registration. Round-table conferences are beir arranged between the Central Midwives Board and th local supervising authorities grouped. Dr. Greenwoo is acting as secretary for the S.E. group of 17 author ties for the purpose of arranging group representative and bringing forward subjects for discussion. Th first conference was held on March 3rd, 1926. Th county council acts as maternity and child welfa authority for an area comprising 6 boroughs, 12 urba and 20 rural districts with a population of 404,99 and the many centres in this area are visited periodi ally by the assistant county medical officer, wh discusses with the medical officer and health visito of the centre matters of interest or difficulty. A regards the puerperal fever and ophthalmia neona torum regulations a considerable number of hospita admit these cases, and 56 nursing associations allo their nurses to attend ophthalmia cases. No arrang ments have yet been made for a second opinion fo puerperal pyrexia and there is no obstetric speciali practising in the administrative county. A tab shows that during the last five years the infa mortality-rate in the area of the county schem compares favourably with that in the rest of Ken In 1926 the figures were for the special area 47·5 an for the rest of Kent 58·0.

The new houses erected in the county numbere 7256 compared with 4466 for the previous yea The shortage is given as about 8000, and Dr. Greenwoo is not satisfied with the progress that is being made t overtake the shortage. He also thinks that i addition to the 235 houses reported as unfit for huma habitation, there were a large number just over th borderline, and that although many property owne fulfil their obligations, there are too many "who attitude is unhelpful from a public health standpoi and short-sighted from their own point of view."

Staffordshire.

Dr. W. D. Carruthers thinks that the vital statisti are much more favourable than might have bee expected as the result of the long industrial upheava The death-rate from all causes was the lowest ev recorded in the county and the infant mortality-ra has only once been equalled in previous years. Th county health visiting area serves a population 321,197, including 15 urban and 14 rural district At the end of 1926 there were 27 combined scho clinics and infant welfare centres and four infa welfare centres. In ten of the larger centres th necessary equipment has been provided for antenat work, and the midwives have been invited to coöperat by bringing expectant mothers to the centre. It expected that as the result of the post-certificat lectures the midwives will take full advantage of th facilities offered. In order to comply with th puerperal fever regulations arrangements have bee made for the admission of cases to hospital for hom nursing if such a course is deemed desirable by th medical attendant, and for the services of a consultan obstetrician in each of the three districts into whic the county health visiting area is divided, while th county laboratory is available for bacteriologic examinations for the whole of the county. Only small proportion of the cases of ophthalmia neonatoru receive hospital treatment. Thus out of 166 case notified 12 were treated as in-patients, five as ou

ients, and the remainder at home. There were ee cases of impaired vision and one of the infants d.

Under the Milk and Dairies Order, 1926, the erinary inspections of herds will only be made en tuberculous milk is complained of by outside horities, or when samples of milk, taken by the nty council inspector, prove to be tuberculous. At onference with the local authorities it was agreed t the county council should take samples of milk tematically throughout the county and relieve the trict councils of this responsibility. Producers of ty milk are to be referred to the County Farm titute for help in reaching a higher standard of nliness. The returns made by the district medical cers of health indicate an improvement in the sing position. Until recently the new houses lt have only been sufficient to deal with the natural rease of the population, but it is thought that 0 of the 3000 houses built during 1926 will be ilable for reducing the number of overcrowded or it houses. "The existing arrears are enormous," a very great improvement may now be expected hin the next few years.

Cambridgeshire.

Dr. Frank Robinson says that the successful experie of the maternity scheme administered by the dcliffe Infirmary, Oxford, has led to negotiations for milar scheme for Cambridgeshire in connexion with denbrooke's Hospital, an essential feature of which uld be the establishment of an antenatal clinic with necessary maternity beds. The administrative nty consists of the borough of Cambridge and six il districts. The borough has its own maternity child welfare scheme and certain duties delegated t under the Midwives Act. There are 56 midwives ctising in the whole county, 54 of whom are trained also act as district nurses. The county council s scholarships for the training of nurse-midwives grants in aid of district nursing associations who loy them. During the year one new association ted work. In the rural districts the nurses visit ut half the expectant mothers, but there are no natal clinics. In the borough the facilities for attendance of expectant mothers at the centres is e used, and it is thought that the antenatal work uld be carried out by an obstetric specialist.

here are now in the county two firms holding ices for the supply of "Certified" milk. The nty council is to take samples for the detection of rculous infection on behalf of four of the rural icts, but the other two prefer to do the sampling themselves. When the tuberculous sample is d the machinery of the Tuberculosis Order will used as being less cumbrous than that of the Act. In spite of considerable activity on the part he sanitary authorities in building houses, it is y possible to close an unfit house. There were notifications of encephalitis lethargica and seven hs, making a total of 50 notifications and eaths since the disease became notifiable in 1919. Andrew J. Laird, the medical officer of health of borough, is of opinion that there is a great improve- in milk production as the result of clean milk petitions.

the borough (population 58,820) there have been houses erected since 1920, 571 by the town cil and 511 by other means. Dr. Laird reports a supplementary housing society has been ed. It is the intention of this society to let their es to people who cannot pay the rents of municipal es and who are in urgent need, because of over- ding or insanitary conditions. The society has d funds by donations and loans at a low rate of est, and sufficient money has been obtained to le the first 22 houses to be begun.

Rutlandshire.

Dr. Christopher Rolleston says that only one-third e mothers in the county have the advantage of d nursing in their confinements. The county council make grants to three nursing associations who employ nurse-midwives. The number of cases attended by midwives was 49, the total births being 299. Medical help was summoned in seven cases and the midwives attended 11 other confinements as maternity nurses. Dr. Rolleston refers to the advantage of periodical medical examinations in securing improved health and longer life, and points out that insured persons can have such from their panel doctors and that other persons can use the tuberculosis, V.D., and maternity centres for a similar purpose. Owing to the small figures the two deaths from childbirth make a high death-rate for the year 1926, but Dr. Rolleston shows that during the last 17 years there have been 5761 births in the county and only 14 deaths from childbirth, which gives a rate of 2·4 per 1000 births. Arrangements have been made with the Stamford Infirmary for the admission of difficult labour and puerperal fever cases. Maternity outfits are being supplied to expectant mothers below cost price and numerous applications for them are received. Dr. Rolleston suggests that arrangements should be made for a consulting obstetrician to visit Oakham and Stamford to see cases where difficulty in labour is anticipated. He would also like to see provision made for the institutional treatment of pneumonia. In 1900 11 persons died from cancer in the county and 18 from pulmonary tuberculosis; in 1926 28 persons died from cancer and only 10 from pulmonary tuberculosis. The health committee has issued a warning notice with regard to cancer of the breast for the purpose of securing early diagnosis and operation. The rheumatic children sent to the Children's Home of Rest, Liverpool, have done well. Out of 722 babies it was found that a comforter was used for 192 and not used for 530.

Three patients had pneumothorax treatment during the year. One has now left the county, but is doing well; the second is also doing well in his sixth year of treatment; and the third, who came from Leicestershire with the whole of the right lung and the larynx involved, so that she could only whisper, and with tubercle bacilli in her sputum, has now greatly improved and her sputum is free from tubercle bacilli. In referring to the Spahlinger treatment, Dr. Rolleston mentions that of eight cases treated at St. George's Hospital in 1913 and 1914 seven are dead and one untraced, and that a patient whom he saw with marked disease and tubercle bacilli in the sputum, who was at first reported to be doing well under this treatment, has just died. There is very little V.D. in the county, but it is difficult to secure continuation of treatment up to a complete cure. The percentage of mental defectives in the county is high, but Dr. Rolleston thinks this is due to extra-good ascertainment owing to the fact that he has completed 17 years in the county in the multiple capacity of medical officer for the maternity, infant welfare, tuberculosis, venereal, and school services. The county council has now adopted the Housing (Rural Workers) Act of 1926 and approved a scheme for its operation.

An outbreak of poliomyelitis took place somewhat later than the Leicestershire epidemic. There were two cases in September, 12 in October, and 3 in November. Three of the cases occurred in one household and two in another. Arrangements have been made under the Milk Act for the inspection of the milch cows in the county by three veterinary inspectors at regular intervals; 10*s.* is to be paid for each visit to the dairy and 1*s.* for each animal inspected. The biological examinations of the milk, when necessary, will be made at Cambridge.

Dunbarton.

Dr. T. L. Thomson says a beginning has been made with the inspection of farms under the Milk Act. The county is administered by an eastern and a western district committee, and the two district committees and the burghs have combined to appoint Mr. James McDougall, M.R.C.V.S., as veterinary inspector for the milk enactments and the Contagious

Diseases of Animals Acts. This appointment puts the work on a much sounder footing. The western district has 136 registered dairies containing 2959 cows. Amongst these the inspector found four tuberculous cows and he took samples from four suspicious udders, the milk from two of which was found to contain tubercle bacilli. These tuberculous cows were slaughtered under the Order. In the eastern district there are 118 dairies and 2642 cows. Among these no tuberculous animals were found by clinical examination, but samples were taken from 15 suspicious udders. These samples were submitted to microscopic examination with negative results. Apparently the biological test was not performed, in which case the time spent by the veterinary inspector in the search for tuberculous cows may have been largely wasted. In the eastern district one herd of 30 Ayrshires was tested with tuberculin and a licence granted for the sale of Grade A (T.T.) milk. It was only possible to inspect the cows in the two districts once during the year, owing to the large amount of time spent in explaining the new legislative provisions. In May a county laboratory was fitted up and in June a notice was received from the Usher Institute that examinations for local authorities would be discontinued from Oct. 1st. By the end of the year the burghs, the education authority, and the hospitals in the county had all arranged to use the new county laboratory. Ultra-violet light treatment is provided by sending the patients to Glasgow hospitals and paying their railway fares when necessary, but it is hoped to establish this treatment in the county at the new clinics which are to be built at Alexandria and Duntocher. The by-laws for seasonal workers are receiving better attention from both the farmers and potato merchants. Almost continuous inspection by the sanitary staff was necessary during the summer at the various camping-grounds, the principal one being between Ardmore and Craigendoran. Water-supply appears to be the chief difficulty. There is considerable activity in the provision of houses to compensate for slum clearances. Over 200 "slum clearance" houses are under construction in the western district and 200 more are to be erected under the 1924 Housing Act. In the eastern district about 150 "slum clearance" houses are under construction and 200 additional houses are being built at Duntocher under the 1924 Act. In the western district there were several cases of scarlet fever and diphtheria notified at dairy farms. In no case did the milk become infected, but the sale had to be suspended temporarily in some cases. During the year, owing to an outbreak of typhus fever in Dumbarton burgh, the joint hospital had to be closed to diphtheria and enteric patients, and the tuberculosis patients were sent home in order to make room for typhus contacts. In the eastern district an unusual occurrence was an outbreak of 88 cases of dysentery. The bacteriological investigation was carried out by the Glasgow public health laboratory, and it appeared to be clear that the origin of the outbreak was a farmer who had suffered from dysentery in Mesopotamia during the war, remained a "carrier," and been the means of infecting the milk. The bacilli discovered were of the dysentery type and closely resembled the Sonne bacillus, but showed serological divergences. Only one of the notified cases died and in this instance there was some doubt as to the diagnosis.

Dumfries.

Dr. John Ritchie states that the greatest degree of overcrowding exists in the parishes of Kirkconnel and Sanquhar. Kirkconnel was also the parish most affected by the coal stoppage. The infant mortality of Kirkconnel for the year was 83·3 as compared with an average of 94·7 for the previous five years. An increased amount of medical comforts was supplied to nursing and expectant mothers on account of the stoppage and took the form chiefly of milk and eggs, with a view to providing a sufficient supply of vitamins. In February an intimation was received from Edinburgh that five consumers of milk from a Dumfriesshire dairy had developed typhoid fever. Investigations showed that a woman milker at th farm had suffered from typhoid in 1904, and had positive Widal and bacilli in her excreta. She wa isolated in hospital for observation. Inquiries di not elicit any history of other cases of typhoid cause by her during the last 22 years. Much is hoped fro the Housing (Rural Workers) Act, which became la in 1926, as it is impossible to close old houses owin to the shortage. A scheme for the supply of wate to a considerable part of the Dumfries district wa under consideration, but the cost was prohibitiv The Thornhill sewage disposal system appears to b the chief source of pollution of the Nith, and the Moffa system of the Annan. In the dairy by-laws it ha been found necessary to make special provision fo cow-keepers who do not sell milk, but sell butter i small quantities at certain seasons of the year. Unde the Tuberculosis Order 77 cows from registere dairies were slaughtered; 57 had "advanced disease, 15 "not advanced," and in five cases n tubercle was found. Of these 77 cows 15 were reporte by the county veterinary inspectors, 36 by veterinar practitioners, and 26 by owners.

The scavenging of the small villages, where th valuation is too small to permit of a special scavengin district being formed, causes difficulties. The refuse frequently tipped over a bank and is apt to cause nuisance by catching fire, and in other ways. It suggested that the refuse should be spread in laye and covered with soil after being laid down.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 10TH, 1927.

Notifications.—The following cases of infectio disease were notified during the week:—Small-po 230 (last week 366); scarlet fever, 2099; diphtheri 1572; enteric fever, 56; pneumonia, 1424; puerper fever, 36; puerperal pyrexia, 95; cerebro-spin fever, 8; acute poliomyelitis, 9; acute poli encephalitis, 3; encephalitis lethargica, 35; dyse tery, 20; ophthalmia neonatorum, 95. There w no case of cholera, plague, or typhus fever notifi during the week.

The cases of dysentery were notified from Amersha R.D. 1, Bristol 9, Leominster R.D. 1, Belford R. (Northumberland) 1, Goring R.D. (Oxford) 1, Cheadle R. (Stafford) 2, Reigate R.D. 1, Denbigh 4; all presumab from mental hospitals.

Deaths.—In the aggregate of great towns, includi London, there was no death from small-pox, 3 (0) fro enteric fever, 76 (13) from measles, 10 (5) from scarl fever, 23 (5) from whooping-cough, 40 (6) fro diphtheria, 67 (14) from diarrhœa and enteritis und two years, and 77 (13) from influenza. The figures parentheses are those for London itself. The deat from enteric fever occurred one each in Willesde Reading, and Salford. The number of stillbirt registered during the week was 263 in the great town including 51 in London.

Apart from the metropolis, the fatal cases of measles we notified from West Ham 1, Brighton 2, Great Yarmouth Bristol 8, Stoke-on-Trent 1, Walsall 1, Derby 4, Chest field 1, St. Helens 2, Warrington 2, Manchester 27, Salford Sheffield 5, Darlington 1, West Hartlepool 1, Newcast on-Tyne 1, Rhondda 1. In the same week 34 fatal cas were notified from Glasgow and 6 from Dublin.

DONATIONS AND BEQUESTS.—Mr. William Thelw Thomas, F.R.C.S., of Allerton, Liverpool, left, among oth bequests, £5000 to University of Liverpool to endow Fellowship in surgical pathology; £5000 to the Roy College of Surgeons, Lincoln's Inn-fields, W.C.; £5000 the Royal Medical Benevolent Fund, for pensions f medical men and their widows; £1000 to the Liverpo Medical Institution for the annual purchase of books reference or journals; his house, 84, Rodney-street, in tru to be used as chambers for medical men so long as t executors shall think fit; and the portrait in oils of hims to Liverpool University.

Special Articles.

EDICAL REQUIREMENTS FOR FLYING S LAID DOWN BY THE INTERNATIONAL COMMISSION FOR AIR NAVIGATION.

PRIVATE PILOTS (OWNER-FLIERS).

. *Licence.*—Every candidate before obtaining a vate pilot's licence (flying machine) will present iself for an examination by qualified medical men cially designated for that purpose by the con- ting State issuing the licence.

. This medical examination shall be based upon following requirements of mental and physical ess :—

istory.—Good family and personal history, with par- lar reference to nervous stability, as to which information l be given in a statement made and signed by the lidate and satisfactory to the examining officer.

ge.—Candidates for private licences (flying machines) not apply for a licence before the age of 17.

eneral Surgical Examination.—The candidate must her suffer from any wound or injury, nor have undergone operation, nor possess any abnormality, congenital or uired, which might interfere with the safe handling of aft under ordinary conditions.

alpation of the abdomen and abdominal viscera, par- arly the pyloric, vesicular, duodenal, and appendicular ns, whenever it reveals any swelling or distinct pain, be completed by a radioscopic and radiographic ination.

ay surgical intervention in the biliary passages or the stive tube, except appendicitis, involving a total or ial excision or a diversion of one of these organs, any omical lesion in the walls of any part whatever of the stive tube, any stricture of its calibre, any calculus or gn body, any peritoneal lesion, established by clinical boratory examinations, will entail rejection. Exception be made for spasmodic strictures not accompanied by troubles and for ptoses compensated by a good minal musculature.

seases of the liver (including those of the biliary ages) and of the pancreas will in cases where it is deemed ssary be verified by laboratory examination, par- arly by radiography as well as by an examination of lood and of the urine, and will entail rejection only if afford indication of the existence of a calculus, tumour, sion involving a persistent impairment of function of organs.

neral Medical Examination.—The candidate must not from any disease or disability which renders him suddenly to become incompetent in the management rcraft. He must possess heart, lungs, and nervous m in a state to withstand the effects of altitude. He be free from kidney disease, and must not present clinical sign of syphilis, nor have any cardiac lesion.

e Examination.—The candidate must possess a degree sual acuity equal to 6/9 for both eyes with correction asses if necessary, the visual acuity being measured by s of a powerful illumination not shining directly into yes of the examinee. Ocular poise, the field of vision ch eye, and colour perception must be normal.

r Examination.—The middle ear must be healthy. andidate must possess an auditory acuity not less than corresponding with the perception of the whispered at 1 metre. The vestibular mechanism must be and not hypersensitive. It must be equal on both

se, Throat, and Mouth Examination.—The candidate possess free tubal air entry on both sides.

Each contracting State shall provisionally fix vn methods of examination, until the details and ninimal conditions of the tests shall have been d by a decision of the International Commission ir Navigation. . . .

The successful candidate will receive a medical icate of acceptance, which must be produced e the licence can be issued. . . .

Any aircraft pilot certificated before June 28th, will be considered as having fulfilled the require- s mentioned above for the granting of a certificate ysical fitness unless he should be found to have thological defect capable of causing a sudden ent.

OPERATING CREW OF AIRCRAFT ENGAGED IN PUBLIC TRANSPORT OR AERIAL WORK.

6. *Licence.*—Every candidate before obtaining a licence as a pilot, navigator, engineer, or member of the operating crew of aircraft engaged in public transport or aerial work will present himself for examination by medical men specially designated by the contracting State issuing the licence.

7. *Preliminary Examination.*—The candidate, before undergoing the examination referred to in the preceding paragraph, must have successfully undergone a preliminary medical examination at which he must have satisfied the minimal requirements as to physical fitness indicated below. This examination will be made, at the option of the State issuing the licence, either by the medical men referred to in the above paragraph, or by any other medical man.

The candidate must have the complete use of his four limbs, must not be completely deprived of the use of either eye, must be free from any active or latent, acute or chronic, medical or surgical disability or infection. He must be free from any injury or wound which would entail any degree of functional incapacity which might interfere with the safe handling of aircraft at any altitude even in the case of prolonged or difficult flight. He must be completely free from hernia, must not suffer from any detectable sensory lesion, and must be free from a history of morbid mental or nervous trouble.

8. Medical supervision, both for the selection and the maintenance of efficiency of the personnel specified in paragraph 6, shall be based upon the following requirements of mental and physical fitness :—

History.—The candidate will be questioned at the first examination concerning his family and personal history.

Examination of the Nervous System.—At the first examination the examination of the nervous system of the candidate shall comprise a full inquiry into family and personal history. The information obtained shall be given in a statement made and signed by the candidate and accompanied, if possible, by a certificate in regard especially to losses of consciousness, fits, and convulsions of all kinds, from the candidate's ordinary medical adviser or a responsible person who has known him for a long time. This statement and this certificate must be deemed satisfactory by the examining medical officer.

The candidate must not present any mental or trophic impairment, pathological tremor, or presumptive evidence of latent epilepsy. Motility, sensibility, tendinous, cutaneous and pupillary reflexes, coördination of movements, and cerebellar functions must be normal. An exception may be made for local peripheral trouble due to accidental section of a nerve branch.

Fractures of the cranium involving the internal table of the cranial box, even without apparent impairment, will entail temporary unfitness during a period of two years from the date of the fracture.

Any presumed nervous syphilis will entail rejection, unless the non-existence of such an impairment is proved by an examination of the blood and an examination of the cerebro-spinal fluid, made with the consent of the candidate.

Age.—Pilots and navigators of aircraft engaged in public transport may not enter upon their duties before 19 or after 45 years of age.

General Surgical Examination.—The candidate must neither suffer from any wound or injury, nor have undergone any operation, nor possess any abnormality, congenital or acquired, which might interfere with the safe handling of aircraft at any altitude even in the case of prolonged or difficult flight.

The rest of this examination is the same as for private pilots.

General Medical Examination.—The candidate must not suffer from any disease or disability which renders him liable suddenly to become incompetent in the management of aircraft. His muscular power must be adequate for the handling of the types of aircraft he will have to pilot or the apparatus he is to use.

He must not have any signs of aneurysm of the large arterial trunks, nor have any cardiac lesion, even if well compensated; the heart must be normal, with normal function; and only respiratory arrhythmia, increase of pulse-rate from excitement or exercise, and a general slow pulse not associated with auriculo-ventricular dissociation will be allowed.

The candidate must not suffer from any acute disability of the lungs, nor possess any cicatricial lesion of the lungs, and must be free from tuberculosis capable of being diagnosed by the usual clinical methods, from tracheo-bronchial

disease of the glands and from pulmonary emphysema, even if slight. However, with regard to the maintenance of efficiency of the personnel specified in paragraph 6, pulmonary emphysema will entail rejection only when the pulmonary capacity falls below 3½ litres at rest after a full exhalation and inhalation, and when the duration of the breath-holding falls at rest below 50 seconds, or only 40 seconds if the candidate is less than 1 metre 65 cm. in height or is of the female sex. In addition, each examination shall include a radioscopy record in doubtful clinical cases.

The candidate must not present any signs of organic disease of the kidneys; these latter must be insensitive to palpation and of normal size. Renal ptosis will entail rejection; this rule, however, will not apply as regards the maintenance of efficiency if no functional trouble is involved. The urine must not contain any pathological element. Affections of the urinary passages and of the genital organs, even blennorrhœa, may entail temporary or definite unfitness, an exception being allowable as regards the maintenance of efficiency in the case of tuberculous orchi-epididymitis in its mild and localised form.

Women Applicants.—Candidates of the female sex must present a normal uterus and appendages. Cases in which surgical intervention has taken place will be considered individually. Any presumed pregnancy will entail rejection. Following confinement or miscarriage, the holder of a licence will be allowed to resume her air duties only after having undergone a new medical examination.

The candidate must not present any clinical signs of syphilis.

Eye Examination.—The candidate must possess a degree of visual acuity compatible with the efficient performance of his duties. Pilots and navigators must possess visual acuity equal to 100 per cent. for each eye taken separately and without correction by glasses, the visual acuity being measured by means of a powerful illumination not shining directly into the eyes of the examinee. Binocular vision, ocular poise, the field of vision of each eye, and colour perception must be normal.

Ear Examination.—The middle ear must be healthy. The candidate must possess an auditory acuity not less than that corresponding with the normal perception of the tuning-forks C (1) 64 vibrations per second, C (3) 256 vibrations per second, and C (7) 4096 vibrations per second, the forks being held perpendicularly to the ground 1 cm. from the auditory tube. The vestibular mechanism must be intact and not hypersensitive; it must be equal on both sides.

Nose, Throat, and Mouth Examination.—The candidate must possess free nasal and tubal air entry on both sides and must not suffer from serious, acute, or chronic affections of the buccal cavity or upper respiratory tract.

9. *Provisional Methods.*—Each contracting State shall provisionally fix its own methods of examination, until the details and the minimal conditions of the tests shall have been settled by a decision of the International Commission for Air Navigation. . . .

10. *Certificate of Acceptance.*—The successful candidate will receive a medical certificate of acceptance, which must be produced before the licence can be issued or renewed.

11. *Re-examination.*—In order to ensure the maintenance of efficiency, every member of the personnel specified in paragraph 6, who holds a licence, shall be re-examined periodically at least every six months, if of the male sex, and every three months, if of the female sex, by medical men specially designated by the contracting State issuing the licence, and the findings shall be attached to his original record. In case of illness or accident also he shall be re-examined and pronounced fit before resuming air duties. The date and result of such re-examination shall be recorded on the licence of the person examined.

12. *Carrying On.*—Any member of the operating crew referred to in paragraph 6, who is able to produce proof that since his last medical examination he has not ceased to perform his duties in a satisfactory manner, and that he has accomplished a total of at least 200 hours of flight within the two years last preceding, may be retained in service so long as his physical capacities as ascertained at his last medical examination are sufficiently maintained, unless there be detected in him a pathological defect capable of causing a sudden disability.

A candidate already holding a licence issued after a medical examination but not valid for public transport or aerial work, may be accepted, subject to the conditions specified in the preceding sub-paragraph, as a member of the operating crew referred to in paragraph 6, provided that he c produce proof that, since his last medical examinati he has not ceased to carry out in a satisfact manner the function in respect of which he appl for one of the licences enumerated in paragraph 6, a that he has accomplished a total of at least 200 ho of flight within the two years last preceding.

LIGHT AND HEAT IN MEDICINE.
AN INTERNATIONAL EXHIBITION.

Lieut.-Colonel F. E. Fremantle, M.P., opened t First International Exhibition of Light and Heat Medicine, Surgery, and Hygiene which was held the Central Hall, Westminster, from Dec. 13th to 16t

Dr. King Brown, medical officer of health Battersea, who presided, emphasised the need caution in sunlight treatment, and the necessity medical supervision in all cases, because so little known of the actual mode of action of the rays.

The exhibition itself was attractively laid out, a there was a wide range of apparatus on view. Probal the commonest type of U.V. (ultra-violet) produ is the quartz mercury-vapour burner, and seve improvements in this have recently been ma The Hewittic Electric Co. showed a burner made vitreosil which cuts off wave-lengths below 25(2800 A.U., and in combination with two me filament lamps gives a spectrum closely resembli that of the sun at high altitudes. A similar res may be obtained by placing a vitreosil screen in fr of a quartz burner, and examples of this meth were also exhibited. The same company also show an A.C. burner which can be lit, without tilting, passing a high-tension discharge through the bur by way of a special electrode. No doubt this elimina the risk of damage by too vigorous tilting, and convenient where a lamp is relatively inaccessi Another improvement is a burner which perm the reversal of polarity without sustaining dama This is shown by British Hanovia Quartz Lamp C but is only obtainable in a small size.

The design of stands has reached a high level. T majority shown are very stable, and allow ev necessary movement. Some, however, are not satisfactory, though none was noticed which co be considered dangerous. Several overhead ty were shown, and these may perhaps be viewed w a certain amount of doubt as fracture of burne with consequent spilling of hot mercury, is impossible though it rarely happens. We would li to see more polarity indicators on lamps, as t majority of burners in use would be damaged by reversal of polarity even for a very short time.

A.C. burners were numerous; a new type, the op limb burner, of Gallois et Cie, and by Kelvin Bottom and Baird is an improvement, as it minimises t shielding of limbs by each other. Open arc lam were also well represented, many forms being av able, and there was also a large variety of carbo giving different types of spectrum. Most of t lamps exposed for sale as suitable for home treatme are of the carbon arc type, some using impregnat or coved carbons, and others apparently plain carbo Lamps burning metallic electrodes are to be seen, a of late have shown considerable improvemen especially in the striking gear and carbon holde Care is needed in manipulating these lamps, bo from the electrical and therapeutic points of vie When replacing electrodes it is easy to get unpleasant shock unless the main switch is op whilst from the therapeutic side it is easy to get severe reaction from comparatively short exposur The metals employed are usually tungsten, ir copper, and aluminium, and the radiation contains considerable proportion of the short wave-leng which are so active in causing erythema. In co nexion with this kind of lamp it is interesting to n that Bellingham and Stanley have introduced a n alloy, the "B.S. Alloy"; this is intended to repla

ngsten, as it costs only one-quarter as much as at metal, and burns even more slowly. The spectrum mewhat resembles that of tungsten, except that it specially rich in radiations in the region 2900–00 A.U.

Portable forms of U.V. lamps and those designed r home use were shown on many stands. They are arly all designed to be run from ordinary house rcuits where the fuses are seldom intended for more an 5 ampères. This is the average figure for the rbon types on starting, and it drops a little once the c comes into action. Various devices are used to viate any chance of overdose. The Ulviarc by the I. Syndicate uses a time clock which can be set to 15 minutes; unless it is set the lamp cannot be itched on and after the lapse of the time indicated e lamp is switched off and cannot be relighted till e clock is set again. This clock and switch may be d separately in a neat case for connecting with any mp not using more than 5 ampères. The action is e same as when it is incorporated with this firm's rtable lamp. The Quain lamp prevents overdosage by ranging that the carbons only burn for ten minutes, ter which they have to be readjusted by hand. These e very important features in any lamp for home eatment, and further points to be looked for are the ssibility of getting shocks by touching bare metal carbons connected to the mains. The majority of e portable lamps now appear to have adequate ulation and control switches. The tendency is to range controls permitting use of the lamp on all rmal main voltages. The carbon type of arc seems be the most suitable for use in patients' homes cause if appropriate carbons and powers are ployed it is relatively weak in the shorter wave-gths, which appear to be the most dangerous when d in unskilled hands. The enclosed quartz mercury-pour lamp can now be had in portable form, but view of the above considerations it does not seem be suitable for use by patients themselves—if this ever advisable. Two such outfits were noticed. e first, shown by the British Hanovia Quartz Lamp ., and called the "Homesun," consists of a small artz burner in a metal hood mounted upon its istance unit; the burner is for direct current only, l can be connected to the main in either direction hout damaging the burner. This lamp consumes) watts from the main. Kelvin Bottomley and ird showed a neat outfit contained in a box about size of a large suitcase consisting of a quartz rcury burner suitable for either direct or alternating rent, with resistances for all voltages and parts for and enabling a patient to be treated in any position. is outfit is intended for medical practitioners who h to treat patients in their own homes or in nursing-nes. It is designed to run off ordinary circuits.

Apart from their therapeutic value ultra-violet rays e many applications in the sciences. Thus the stfield College (University of London) showed an eresting series of experiments with U.V. rays on nts. It appears that the effect of unscreened U.V. s is a definite retardation of growth, but when ens of various glasses are used hardly any difference ween controls and experimentals is noted. This gests that the plant, whose metabolism depends irely on the sun, is unable to make use of—and ven damaged by—wave-lengths shorter than those sun itself emits. U.V. rays are also being used y widely in optics. Kelvin Bottomley and Baird wed U.V. lamp for ophthalmoscopic work and roscope illumination, and a type with a filter ing off all visible light which would be suitable for in clinic, especially for ringwork cases. R. and J. k showed microscopes, spectroscopes, and spectro-ers, and Carl Zeiss exhibited a variety of micro-es and illuminants for ordinary polarised and chromatic light. They also had an electric thalmoscope on view. U.V. water-sterilisers were wn by Kelvin Bottomley and Baird and the ittic Co. The latter company's steriliser consumes mpères and delivers sterile water at a rate of gallons per hour. The taste of the water is unaffected, and we are informed the method is used by a large aerated water firm. The sterilisers can be obtained in very large sizes suitable for even the largest quantities of water.

High-frequency and diathermy machines were on exhibition, but there appear to be few changes, except for the introduction by Kelvin Bottomley and Baird, in conjunction with Gallois et Cie, of evacuated quartz electrodes for high-frequency machines. These electrodes contain a little mercury and therefore, it is claimed, emit ultra-violet radiation. A spectrograph is given showing a typical mercury spectrum said to have been obtained from one of these electrodes. Quantitative details are not given, but the emission must be very small unless the electrode is a more efficient generator than the mercury-vapour burner.

The Chloride Electrical Storage Co. exhibited a very wide range of storage batteries. They are a decided improvement upon the dry cell for galvanic treatment, and for radium balances and electroscopes they are invaluable. Portable unspillable types are available for surgical lamps, cauteries, &c. For scientific institutions they are useful for providing a steady source of energy.

MEDICINE AND THE LAW.

Insanity as a Reason for Divorce.

THE legal situation regarding divorce for insanity varies greatly in different countries, as was brought out recently in a report made by Dr. Boven at a congress at Blois.[1] In France insanity is no longer considered a reason for divorce. A law passed in 1792 admitted insanity as a cause for divorce, but this was annulled by the Code Napoléon and divorce cannot now be obtained for this cause. The law in the United States varies according to State legislation. In some States insanity is considered a sufficient cause for divorce after six years (Idaho) or after ten years (Washington) of confinement. In other States the marriage may be annulled on grounds of epileptic or alcoholic mental disorders. In Sweden divorce may be pronounced if one of the parties is suffering from a mental disease which has lasted for three years of married life and if there is no hope of permanent cure. Since 1910 Germany has allowed divorce for insanity if it has lasted for three years, is sufficiently serious to destroy mental relations between the couple, and is considered incurable. A Swiss law passed in 1912 allows divorce if cohabitation is no longer possible, if the disease has lasted three years, and has been pronounced incurable by experts. In practice, divorces for insanity are fairly rare; out of 21,025 divorces granted in 11 years, only 435 (2 per cent.) were for mental causes. Dr. Boven weighed up the pros and cons of divorce for insanity. Among the former he placed the interests of the healthy husband or wife, and the fact that, in those countries where divorce is not allowed, efforts are often made to frustrate the law by bringing forward other motives for divorce. Against divorce, he argued that mental diseases are not essentially different from others, that it is almost impossible to say when a case is incurable, as cures are often effected after long years of confinement, and that doctors might become liable for damages for having broken up the home. On the whole, however, he was favourable to divorce on the grounds of insanity, but with certain restrictions.

Burning of Body to Avoid Inquest.

At the Lewes Assizes on Dec. 10th a woman pleaded "Guilty" to the charge of destroying the dead body of a five-months' old nurse-child at Brighton with intent to prevent an inquest being held. The prosecution alleged that she had burnt the body and scattered the ashes along the roadside. She had not registered the child. A superintendent of police stated that inquests had been held at Portsmouth

[1] See Paris Médicale, 1927, xvii., 287.

in 1913 on two nurse-children who were in the care of the accused and that in one of these two cases the coroner had spoken strongly of her conduct. Mr. Justice Horridge, describing her as a very wicked woman, passed sentence of nine months' hard labour.

It may be of interest to recall that the charge in the Lewes case was identical with that in R. *v.* Price which occasioned the elaborate exposition of our burial law by Mr. Justice Stephen at the Cardiff Assizes in 1883. At that date there was a general idea that to dispose of a body by burning—a practice opposed to the common sentiment of the country—was illegal. Price had put a dead child's body in a 10-gallon cask of petroleum and had set the cask on fire in a field. A crowd collected, earth was thrown on the body, the flames were extinguished, and Price was charged, first, with having prevented the holding of an inquest, and, secondly, with having attempted to burn the body. There was evidence that the coroner had told him that, unless a medical certificate was forthcoming, an inquest would be held. Price was acquitted on both charges, but Stephen's address to the grand jury remains an important authority on the coroner's right to hold an inquest, the limitations on his power to interfere with funeral arrangements, the offence of obstructing an inquest, and, lastly, the lawfulness of cremation. Stephen announced that he could find no authority for the proposition that it was a misdemeanour to burn a body; in the absence of such authority he declined to declare it a crime. He held cremation to be lawful provided that it was so conducted as not to amount to a public nuisance at common law, and provided also, of course, that the body was not burnt in an attempt to defeat the course of justice. "It may be that it would be well," he said, "for Parliament to regulate or to forbid the burning of bodies, but the great leading rule of criminal law is that nothing is a crime unless it is plainly forbidden by law." He reaffirmed his opinion in R. *v.* Stephenson in the Court of Crown Cases Reserved in the following year. The result was a movement to establish crematoria, the law having been ascertained to be no longer hostile, though Parliament did not deal with the subject until the Cremation Act of 1902.

"*Rum and Butter Toffee.*"

The Sale of Food and Drugs Acts continue to set nice problems to magistrates. The Bishops Auckland bench had to deal with an inspector's information under these Acts arising out of the purchase of something described as "Riley's Rum and Butter Toffee." A confectioner was charged with selling to the prejudice of the purchaser an article not of the nature, substance, and quality demanded. The manufacturers, who had supplied it under a warranty, accepted responsibility and were proceeded against for giving a false warranty. Analysis showed the toffee to contain both rum and butter; it had the flavour of both, but it also contained a large percentage of coconut fat which had been added to prevent the toffee from being too sticky. The case stated by the magistrates, who convicted the manufacturers and imposed a fine of 40*s*., set forth that toffee made with no fat but butter would be greasy both to touch and taste, that coconut fat was nutritious and harmless, and that toffee made partly of coconut fat had for years been sold as "rum and butter toffee." It was also stated that the flavour of rum and butter could be produced synthetically and that, if such flavouring were used, the substance which resulted would be properly called "rum and butter-flavoured toffee," not "rum and butter toffee." The King's Bench Division, by a majority of two judges to one, upheld the magistrates' conviction. Branson and Avory, J. J., said toffee was something which could be made with various fats, and the description "butter toffee" must mean toffee in which the only fat used was butter. Talbot, J., dissenting, said he thought "rum and butter toffee" meant toffee with a substantial amount of rum and butter in it; in his view the manufacturers should have been acquitted. There seems a good deal to be said for the latter opinion.

Correspondence.

"Audi alteram partem."

THE PRESENT POSITION OF THE VOLUNTARY HOSPITAL.

To the Editor of THE LANCET.

SIR,—Having just completed a ten months' tou in Australasia, Canada, the United States, and Grea Britain investigating problems of medical education research, and administration, in which the presen and future of the voluntary hospital have naturall formed an integral part, I have read Dr. Graham Little's address with considerable interest. Th more so, because my recent experiences amongst som of the finest of the self-supporting hospitals have le me seriously to doubt the alleged superiority of purel traditional methods, and Dr. Little's address ha done much to resolve those doubts. His thesi appears to be that the voluntary system must b maintained intact by all means in our power, becaus "it is to be borne in mind that the alternative to th voluntary system is exactly this bureaucratic contro which would necessarily be many more times expen sive." I venture to believe that Dr. Little's addres itself furnishes some destructive evidence against hi thesis, whilst his reason appears to be demonstrabl wrong.

Between the years 1913 and 1925 Dr. Little state that the cost per bed has increased by 100 per cent., an of this present-day cost of £200 per bed, some £9 has to be found by charitable appeal. This appea has to be made to the most heavily taxed people i the world, already straining under burdens of contri butions to upwardly rising poor rates, unemploymen doles, insurance schemes, and the like, and yet thi steadily increasing medical and national pauperisatio of the people is to be maintained intact by every mean in our power.

Dr. Little states that the middle class remain outside this system altogether, but that it is hig time that some provision was made for their prope medical treatment. It is difficult to understand ho the voluntary system of charitable doles to voluntar hospitals, largely and increasingly unable to meet th present requirements of either patient or advancin medical science, is to cope with this new burden. Bu is it not a fact that post-war financial stringency i forcing this very middle class into voluntary hospital intended originally, at all events, for the indigent sick

Dr. Little's article would appear to prove that thi is so, for he quotes with apparent approval that ther are now 1600 more hospital beds in London than ther were before the war, and this fact is adduced a evidence of progress and very vigorous life. To me i appears as the exact contrary. It looks as thoug there were a rising tide of medical pauperisation, of constant seeking of something for nothing, of national decay of morale, and of an ever-increasin tendency to put one's own burdens on to someon else. Patients who now seek hospital aid are clearl seeking the charity of others, and are doing so appa rently in constantly increasing numbers. The positio is fraught with possibilities of disaster, and the mai tenance of the voluntary system, with its fals economics, its inability to meet the constantly risin costs of medical science, and the obvious impossibilit of such a system coping with the demands of advancin knowledge in the progress of medicine must inevitabl bring the day of disaster appreciably nearer.

Dr. Little's paragraph on "paying beds" is also I think, condemnatory of the system he seeks to defen for it simply perpetuates the vicious circle. Willin to pay board and lodging, but unable to pay fo medical advice, such patients are to swell the alread swollen and inadequate hospital accommodation an are to be a further charge on medical, if not publi charity. To relieve the financial impecuniosity of th voluntary hospital at the further expense of th

medical profession is a curious reason for maintaining such a system intact. At the least, the Chancellor of the Exchequer should be invited by Dr. Little to remit all medical income-tax.

If the present voluntary hospital system is in quite the parlous condition set forth by Dr. Little I am unable to visualise its coping successfully with future progress in medical science, nor do I see the voluntary hospital adapting itself to such progress. It is a financial impossibility. Nor can it be supported by the manifest fables which someone has been telling Dr. Little of American hospital medical service. I visited many of the leading Canadian, Eastern, and Middle-West American hospitals in the early part of this year, and nowhere did I see the truly humorous state of affairs described by him. On the contrary I saw large, efficient, well-endowed, and *self-supporting* medical centres, combining hospital and medical school, and having seen such self-supporting hospitals I am quite unable to accept Dr. Little's contention that the voluntary system is the *only* alternative to this, and my, detestable bureaucratic control. It is because I so cordially agree that "State-aided institutions are the product of a weak-kneed generation" that I would earnestly beg him, and those who think with him, to investigate, as has been my own good fortune, other systems, before nailing the flag to the mast of a decadent and dangerous voluntary system, under the mistaken belief that bureaucracy—the present-day menace of democracy—is the only alternative.

In conclusion I should like to assure Dr. Little that these remarks are not made in that, to me, most detestable of all forms of criticism, the purely destructive. On the contrary, experience has led me to believe that upon the wise solution of an acute and difficult problem depends, not only the welfare of those magnificent institutions which he has so much at heart, but also that of the nation itself, and if this is so, then no stone should be left unturned to secure that future success to which the past and present splendid effort of British medicine so justly entitles it.

I am, Sir, yours faithfully,

RICHARD J. A. BERRY.

Dean of the Faculty of Medicine, University of Melbourne.

Dec. 17th, 1927.

To the Editor of THE LANCET.

SIR,—Dr. Graham Little's address touches upon a wide range of important subjects. In regard to medical education, perhaps the most significant change that has ever taken place is the subsidy granted by the Treasury through the Board of Education. For this subsidy has averted a bankruptcy in a system whose success depended, up to 1858, the date of the Medical Act, solely upon the fees of the pupils, and indirectly upon fees paid for examinations. Since, the old universities, owing to their endowments and the new, mainly from Governmental support, have generously promoted medical education and relieved the teachers of a burden that was rapidly becoming intolerable and that would in all probability have produced disaster. As a business proposition education is impossible; therefore it must be supported from other and trustworthy sources.

If the present hospital system is to reach a position in which it will adequately meet the needs of the people there should shortly be made a demand by the medical profession for further and free education and training of qualified and registered doctors to become expert physicians, surgeons, and specialists of all kinds; and for such a service an appeal should be made to the Treasury so that a new and additional system of medical education and training, worthy of the standing of British medicine, shall be established above and above the present system for the education and training of the ordinary doctor. Our present medical schools have as much to do as they possibly can; and, if report be true, many of them are suffering, on the one hand, from a plethora of students and, on the other hand, from a paucity of facilities for the technical training of the student in the work that awaits him, and of which he is expected to know and to be practised in when given a diploma or degree for placing him on the Medical Register.

It would appear that Dr. Little has hardly appreciated the fact that the voluntary hospital system is rapidly becoming transformed into the provident one, and that the success he records is mainly due to that fact. Many of the so-called voluntary hospitals are entirely supported on the provident system—weekly contributions from the workmen. Indeed even the hospitals with medical schools attached are doing their best to get themselves on that thesis so as to obtain a security in income. Were this transformation not taking place on a larger and increasing scale the plight of the hospitals would indeed be a serious one. I believe it would be better if all were now to open their eyes so as to see the new movement and to be ready to guide it so that the medical services for the people shall continue on a sound footing and be timely rearranged to meet the conditions attendant upon the provident system which is rapidly displacing the old, voluntary or charity, with their serious limitations in many directions. I am, Sir, yours faithfully,

Cambridge, Dec. 19th, 1927. JOSEPH GRIFFITHS.

THE PREVENTION OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—From your annotation on this subject in THE LANCET of Dec. 10th (p. 1247) I infer that the London County Council are not convinced that the claims made for toxin-antitoxin immunisation in diphtheria are fully substantiated. It has been said [1] that no case clinically resembling diphtheria occurring in a Schick-negative reactor should be accepted as diphtheria until the Klebs-Löffler bacillus has been isolated and proved to be virulent by a guinea-pig test, a condition with which I am in full agreement, providing the same routine is followed in all cases in non-immunised subjects before the diagnosis of diphtheria is accepted. If this procedure were followed I have no doubt a very considerable percentage of cases regarded as diphtheria on the result of a Schick test would have to be rejected as "diagnosis not sustained."

It would be interesting to know exactly how much of the apparent increase in diphtheria during recent years can be attributed to the practice of medical men taking a swab from the throat—often a perfectly clean throat—and on organisms resembling the Klebs-Löffler bacillus being found, notifying the case as one of diphtheria. During 1925 the number of admissions to the Birmingham Fever Hospital for diphtheria was 1999, but of these 290, or 14·5 per cent., were found to be errors in diagnosis.

"Of 772 cases in which the medical practitioner had obtained a positive bacteriological report, 391, or 50·5 per cent., on admission showed no clinical evidence of diphtheria." [2]

If we examine the figures for the London area we find that during 1925 of the 9247 total admissions to M.A.B. hospitals for clinical diphtheria, the original diagnosis was held to be wrong in no fewer than 2366 cases, or 26·0 per cent. In addition 1004 cases were admitted as bacteriological diphtheria.[2]

Sir George Newman has stated:—

"The number of cases admitted (to the Metropolitan Asylums Board Hospitals) with mistaken diagnosis is higher than it was 15 years ago. Between 1911 and 1914 the percentage of cases of diphtheria wrongly diagnosed was 12·7 in 1911, 12·9 in 1912, 15·6 in 1913, and 11·4 in 1914, while for recent years the proportion has more than doubled." [3]

Little wonder that Drs. Harries, Macfarlane, and Gilhespy say [4]:—

"Every year many hundreds of people—adults and children—who are so unfortunate as to harbour harmless

[1] Medical Research Council, Special Report Series No. 115, p. 17. [2] Ibid., p. 22.

[3] On the State of the Public Health. Annual report of the the Chief M.O. of the Ministry of Health, 1926, p. 54.

[4] THE LANCET, Sept. 24th, p. 646.

diphtheroids, are hurried into infectious diseases hospitals upon the strength of a morphological diagnosis of a culture from the swab, to the needless anxiety of relations and at considerable cost to the community."

In fact, it is common knowledge that a large proportion of cases admitted to isolation hospitals as diphtheria show no clinical signs of that disease.

The mere fact of there being a lull in the number of notifications of diphtheria following immunisation does not necessarily prove anything. During the summer I received a visit from a Swedish medical officer of health, when amongst other matters we discussed diphtheria. He told me it had almost disappeared from his town of late years, and on my asking if it was due to toxin-antitoxin immunisation my friend replied: "Certainly not. Whatever be the cause it is not immunisation, for I have not practised it and do not intend to do so, as I do not believe in it." Up to the time of writing we have had this year a very considerable fall in the number of notifications of diphtheria in Northampton, and for some three months it has apparently been almost absent from the town, there not having been a single case in a child of or under school age. Again this happy state has not been brought about by toxin-antitoxin immunisation, for it has never been attempted here. The marked fall in the numbers for 1927 is no more due to immunisation than the rise in 1926 was due to the want of it. How easy it would have been for the "Schickites" to have claimed it as a brilliant success had we practised immunisation even to a limited extent.

This is not written with the desire to prove that immunisation is useless, but merely as a reminder how careful one should be in drawing conclusions where the amount of available evidence is very limited. From what one has heard first hand from those who have worked in hospitals where Schick's method was practised, I feel for the present we must return for Schick the same verdict you brought in for B.C.G.—viz., not proven.[5]

I am, Sir, yours faithfully,

STEPHEN ROWLAND,
Dec. 14th, 1927. Medical Officer of Health, Northampton.

To the Editor of THE LANCET.

SIR,—Under this heading you state in your issue of Dec. 10th (p. 1247): "It is not surprising, therefore, that the London County Council should have decided to re-examine the need for taking fresh measures to combat diphtheria." May I beg to point out that it was only on my request that any reconsideration of their policy in this matter was undertaken, and their decision to do nothing in favour of active immunisation of school-children was a confirmation of their previous policy in this matter. You will find in referring to the report that a suggestion was made (by myself) for an experiment to be tried in two or more of the Council schools, in which diphtheria is always rife. By the voluntary immunisation of as many children as possible during the next 12 months one would then be able to compare the results with schools in which immunisation had not been tried. As is well known, the metropolitan borough councils are very little in touch with children of the age-group 2 to 5 years, so that only a fraction of the future school-children can possibly be immunised by the borough medical staffs. It is mere window-dressing to suggest, as the report does, "that those parents who desire that their children should be protected by immunisation should be given every opportunity to satisfy their wishes." Obviously parents have had very little education on this subject, and the facilities afforded by the borough councils do not apply to more than a small proportion of those children who will eventually attend school; whereas a control experiment such as I suggested would have afforded some definite evidence of the protective value of immunisation against diphtheria.

I am, Sir, yours faithfully,

Chiswick, W., Dec. 14th, 1927. STELLA CHURCHILL.

[5] THE LANCET, 1927, i., 936, and August 20th, p. 403.

SPINNERS' CANCER.

To the Editor of THE LANCET.

SIR,—If we accept Dr. Robertson's views on th origin of scrotal cancer in mule-spinners it means tha a non-specific irritation such as a blow or frictio ("mere traumata" as Cheatle put it in a recent issue does and can, per se, cause cancer. The modern tren of opinion is in the opposite direction. The kerat genic agents, such as certain petroleums, coal product arsenic, actinic, X, and radium rays have been foun to be, statistically and clinically, closely associate with the appearance of malignant growths.

Every substance which irritates the skin has son special property, to which it owes its injurious activit This physico-chemical quality may be hygroscopi hydrolytic, protein-precipitant, oxidising, reducin keratogenic, dependent on solubility or volatility, ar so on. Without one or more of these characteristi both outside and inside the body, the agent is iner It cannot produce a dermatitis, much less a cance The purely physical injuries by themselves have n been shown conclusively to be keratogenic, neoplastic, as I have suggested elsewhere.[1] Eve though we accept the dictum of Murray,[2] "that it clear that cancer is not the direct response of th tissues to some special substance" the weight clinical and experimental evidence is strongly favour of some petroleum oils being important facto

We may accept Dr. Robertson's view that th constant friction of the overalls against the left aspe of the spinner's scrotum will denude the protectiv corneous layer from that part. The tissues will the be in a ready state to be acted upon by the perpetu rubbing in of any keratogenic material. The amou may be small—or even very small, as Dr. Roberts contends—but no mule-spinner in my experien admits that the scrotum is quite free from lubricati oil.

I am, Sir, yours faithfully,

Wigan, Dec. 17th, 1927. R. PROSSER WHITE.

TOXÆMIAS OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—Referring to our recent report to the Medic Research Council on the investigation of cases toxæmia of pregnancy, Dr. Chalmers Watson asks question and makes a suggestion in the letter whi you published in your last issue. May we be permitt to reply to his observations? Dr. Watson remar that "in any series of 200 cases of toxæmia pregnancy the examination of the urine would reve a marked degree of bacteriuria in at least 90 per cen of the cases" and that "the examination of t intestinal contents as voided would reveal unmista able evidence of a high degree of abnormal putrefacti in every case." He suggests further that "it is alo these lines that we will ultimately find the comm cause, if such exists."

We stated in our report that there had been a fu clinical examination of every case, and that cases infection of the urinary tract had been excluded fro the series. This examination naturally included bacteriological examination of the urine, and we wi to repeat, in reply to Dr. Watson's question, that no case was there a bacilluria or pyuria, still less "marked degree of bacteriuria." Further, even t most pronounced cases of renal infection do not, as rule, show the syndrome characteristic of th toxæmias of pregnancy. We have, however, noted t development of pyuria in a number of our cases. Th did not occur during the acute toxic stage of th illness, but after such an interval that it is to regarded as a complication and not as a cause of th condition.

As regards intestinal putrefaction we find it mo difficult to speak, for bacteriological examination

[1] The Clinical Incidence and Aspects of the Trade Sk Cancers, Jour. of State Medicine, 1927, xxxv., No. 9.
[2] Murray, J. A.: Research Defence Society, July, 19 p. 12.

he stools was not carried out. If, however, we take Dr. Watson's criterion—"the sound use of the naided senses"—then we can say that while constipation was common we have not noted any ndication of "intestinal putrefaction" as we understand the term. If intestinal putrefaction or "intesinal auto-intoxication" be the cause of the toxæmias f pregnancy, as suggested by your correspondent, ve find it difficult to explain the good therapeutic esults which are obtained by two such different nethods of treatment as the Dublin and the troganoff methods. The success of the Dublin nethod appears to support Dr. Watson's idea that ntestinal toxæmia is an important causal factor inasnuch as colonic lavage is an essential part of the reatment. On the other hand, Stroganoff, who reports ven better results, never washes out the colon, and mpties the rectum only if it is loaded. Again, our wn results are as good as those reported by the)ublin school, but the only important factor in ommon is starvation. We do not deny, of course, hat the absorption of toxic waste products from the ut must have an injurious effect, and we advocate he stimulation of elimination by the bowel in this s in any other toxic state. We consider that more nportant than intestinal stasis is the effect of the igestion of protein. Our insistence upon this point s an essential part of our method of treatment has, 'e regret, escaped the comment both of your corre-)ondent and of our reviewer in your columns. It is gnificant, we think, that both in the Dublin method id in our own great stress is laid on the withdrawal ' protein from the diet. We state in our report our easons for suggesting that protein acts deleteriously such cases in virtue of its protein structure and the sulting breakdown products and not because of its trogen content.

We are, Sir, yours faithfully,

J. N. CRUICKSHANK,
J. HEWITT,

MEMORIAL TO THE LATE PROF. FRANCIS MITCHELL CAIRD.

To the Editor of THE LANCET.

SIR,—A number of the friends of the late Mr. Francis itchell Caird, a former lecturer on surgery in the xtra-Mural School and professor of clinical surgery the University of Edinburgh, having expressed a sire to perpetuate his memory in the Edinburgh edical School, a committee was appointed by the edical Faculty of the University and the Council of e Royal College of Surgeons to consider what step ould be taken for this purpose.

The committee and the two bodies which it repreited decided that the memorial should include a ze and medal open for competition to graduates of University and Licentiates and Fellows of the yal College of Surgeons of Edinburgh who have died for two years in Edinburgh and have been alified as practitioners for not more than seven ars. The prize, offered biennially, will be awarded the best essay in surgery or surgical pathology sed on personal observation and research, the subject ng chosen by the candidate.

Subscriptions of £1 1s. and upwards will be gratefully eived. Those who have not been approached ectly by the committee and are desirous of subibing are invited to send their subscriptions by que or postal order, payable to the Francis Mitchell rd Memorial Fund, per the accountant of the iversity, and addressed to him at the University of inburgh, Old College, Edinburgh.

We are, Sir, yours faithfully,

ALEXANDER MILES,
President, Royal College of Surgeons of Edinburgh.

J. LORRAIN SMITH,
Dean of the Medical Faculty, University of Edinburgh.

dinburgh, Dec. 17th, 1927.

MERCUROCHROME INTRAVENOUSLY.

To the Editor of THE LANCET.

SIR,—In response to the wish expressed by Mr. W. H. Martindale, Ph.D., in his letter to THE LANCET of Dec. 10th I send a brief report of experience with the intravenous injection of mercurochrome 220 in cases of acute and chronic gonorrhœa in adult males. Last year 14 cases of gonorrhœa under my care as out-patients in the V.D. department at Guy's Hospital were treated with a series of intravenous injections of mercurochrome 220; three of these cases were suffering from acute gonorrhœa with no complication, the remainder were in the chronic stage and suffering from chronic prostatitis, seminal vesiculitis, or both. The scheme of treatment was as follows:—

First day	..	10	c.cm. of 0·5	per cent. mercurochrome.
At intervals of 2–3 days later		20	,, 0·5	,, ,,
		10	,, 1·0	,, ,,
		10	,, 1·0	,, ,,
		20	,, 1·0	,, ,,
		20	,, 1·0	,, ,,
		20	,, 1·0	,, ,,

Ten of the 14 cases completed this series of injections; in a few there were slight variations in the time intervals between injections and in the quantity of the injections. No serious or marked reactions were encountered following injections in any of these cases, but slight reactions were noted in five cases—viz.: (1) transient vomiting and diarrhœa, (2) vomiting only, (3) a feeling of general malaise, (4) diarrhœa for two days, (5) abdominal pain but no vomiting or diarrhœa.

There appeared to be no definite correlation between these reactions and the concentration of the injection or the quantity of mercurochrome; the relationship is expressed below.

No. of injection.	Quantity.	Concentration.	No. of slight reaction.
10	10 c.cm.	0·5 %	2
5	20 c.cm.	0·5 %	1
22	10 c.cm.	1·0 %	2
22	20 c.cm.	1·0 %	2

In all cases, with one exception, further injections were given following the reaction and in one only was a second reaction experienced. In three of the cases under treatment the urine or urethral discharge was noted to be coloured pink; this was associated with a reaction (vomiting) in one case only. All the cases under treatment were young adult males attending as out-patients after their day's work had ceased; apart from the urethritis or its complications they were all in good general condition.

The injections administered were from bulk solutions of mercurochrome in distilled water, which were stored in glass flasks in the dark; such solutions were used up to 14 days from the date of preparation. In two cases the mercurochrome solutions utilised for the series of injections contained 50 per cent. glucose, no reactions were experienced in either of these two cases.—I am, Sir, yours faithfully,

Devonshire-place, W., Dec. 13th, 1927. V. E. LLOYD.

THE REMOVAL OF TONSILS: A "BLOODLESS" METHOD.

To the Editor of THE LANCET.

SIR,—Although I have had a vague knowledge of the existence of a La Force guillotine and a dubious opinion on its "bloodless" surgery for some time, it was not until this year that I saw it in use.

Feeling that there may be many, who, as I was, are ignorant of its value, I venture to bring to your notice an instrument which has been in constant use in America since 1914. Very briefly described it is a guillotine of the Sluder type, but possessing two blades, one a crusher and hæmostat, the other a cutter. The tonsil is engaged in the fenestra of the

instrument and the crushing blade forced down external to the capsule in the usual way. The crusher is now held firmly in position by a screw and thread arrangement for five minutes, accurately timed by watch or sand-glass, as used for timing egg-boiling. The screw attached to the cutting blade is now brought into action and the tonsil cut off just medially of the tissues held by the hæmostat blade. It is then removed by forceps. The screw holding the hæmostat down is now turned in opposite direction and the guillotine removed.

In favourable cases the tonsils may be enucleated with the loss of only a drop or two of blood, just enough to colour the mucus in the pharynx: there is no need for swabs—and in my cases there has been no bleeding later. It must be acknowledged that there is an occasional failure, for the instrument is not so easy to use as the O'Malley or Ballenger guillotine, then resort must be had to dissection. But the same occasional failure must be laid to all guillotines, as I am certain that there are tonsils, though very few, which can only be removed by dissection. I am convinced that wherever possible the guillotine should be used as no dissection operation that I have done myself, or seen others perform, leaves such a clean and regular fossa or causes so little trauma.

A very similar instrument, but one which I have not seen, was devised by W. Hill and G. Elphick in 1914, and I should be very interested to know their views on the method after this lapse of time.

I am, Sir, yours faithfully.

Manchester, Dec. 6th, 1927. LINDLEY SEWELL.

ALKALI TREATMENT IN FEVERS.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Osman, my results are very relevant to the question of the alleged benefit of alkalies in preventing nephritis in scarlet fever, because we have found on a former occasion that, if the alkali debt of the tissues, incurred in the acute stage, is repaid during that stage, no evidence can be obtained of any acidosis throughout convalescence. To confirm this observation, I have recently tested the alkali tolerance of 62 patients in the third week of disease whose urine had been rendered alkaline during the acute stage by repeated four-hourly doses of 1 to 2 g. of alkali (doses according to age).

The urine of a normal child on a mixed diet can be usually rendered alkaline with 5 g. of soda and that of an adult with 10 g. In this group, in 6 cases the urine was rendered alkaline with 1 g., in 13 with 2 g., in 18 with 4 g., in 16 with 5 g., in 4 with 7 g., in 2 each with 8, 10, 12, and 14 g. respectively. Those needing the larger doses were adults and adolescents, those with smaller doses were children. These doses were administered in the same manner as in the acute stage, each specimen of urine being tested with litmus immediately on passage. It will be seen that the alkali tolerance of these patients is rather less than normal, indicating that there is no alkali deficiency during convalescence after treatment with alkalies in the acute stage. Moreover, the urine remained alkaline in 50 per cent. of the cases for the succeeding 24 hours after stopping their administration.

I think, therefore, it is a justifiable conclusion from my experiment, extending over 17 years and 8000 cases, that, if the incidence of nephritis is almost identical in those with a deficient alkaline reserve and those whose alkaline reserve has been restored to normal, such a deficiency cannot play any very important part in the ætiology of this particular complication.—I am, Sir, yours faithfully,

B. A. PETERS.

Ham Green Hospital, Bristol, Dec. 19th, 1927.

ELIZABETH GARRETT ANDERSON HOSPITAL.—On Dec. 15th the foundation-stone of the new extension building was laid by Sir Alan Garrett Anderson, the son of the founder. The sum of £70,000 has been raised towards enlargement of the hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

MEDICAL AND DENTISTS ACTS AMENDMENT BILL.

IN the House of Commons on Friday, Dec. 16th, Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) in moving the second reading of the Medical and Dentists Acts Amendment Bill, said that the Bill embodied an agreement between the Irish Free State and this country which was designed to meet an administrative problem resulting from the establishment of the Irish Free State and the legislation consequent thereon. As a result of that legislation the General Medical Council ceased to exercise any authority or control over the medical profession in the Irish Free State, and also ceased to be able to place on the Register here students who obtained their medical qualification in the Irish Free State. That position was regarded on both sides as unsatisfactory and negotiations had been taking place for some time. In the meanwhile by an interim arrangement the General Medical Council had agreed to accept for the Medical Register here students with qualifications obtained in the Irish Free State. One of the objects of the Bill was to validate that arrangement. An agreement was reached in the early part of this year which was set out as Part 1 of the Schedule of the Bill. In this matter the British Government had been assisted by Sir Donald MacAlister, the President of the General Medical Council, and the agreement had the concurrence and the support of the Council. On the one hand the General Medical Council would continue to admit to the United Kingdom Register all persons who prior to the establishment of the Irish Free State would have been admissible in respect of qualifications obtained in the area which was now the Irish Free State. Secondly, they would have all the power formerly possessed by them of controlling the examinations giving the right of such admission so far as was necessary for keeping the United Kingdom Register. On the other hand, the Irish Free State would establish an Irish Free State Register and would have complete control of that Register in the Irish Free State. Provision was made for admission to the Register on equal terms of all persons on the United Kingdom Register. The position in regard to the Dentists Act was practically similar, and it was embodied in Part 2 of the Schedule. The agreement required legislation in both countries, and in the Free State legislation had been passed to give effect to the medical part of the agreement and had received the Royal Assent. The legislation in regard to the dental side in the Irish Free State would involve two Bills, and he understood that that legislation was now going through. He thought that this was a happy solution of the difficulties that had arisen.

The Bill was read a second time.

NURSING HOMES (REGISTRATION) BILL.

On the consideration of the Nursing Homes (Registration) Bill,

Captain CAZALET moved the following new clause to give power to the Minister of Health to exempt Christian Science nursing homes:—

"(1) The Minister of Health may grant exemption from the operation of this Act in respect of any nursing home, as respects which he is satisfied that it is being or will be carried on in accordance with the practice and principles of the body known as the Church of Christ Scientist. (2) It shall be a condition of any exemption granted to a nursing home under this section that the nursing home shall adopt and use the name of Christian Science Nursing Home. (3) An exemption granted under this section in respect of a nursing home may at any time be withdrawn by the Minister if it appears to him that that home is no longer being carried on in accordance with the said practice and principles."

He said that the first clause of the Bill made it compulsory for any nursing home in the future to have in charge of it a qualified medical doctor or a qualified nurse. The method of healing disease as practised by Christian Scientists was entirely different from that of the medical profession. It was obvious, therefore, that if there was to be a qualified medical man or a qualified nurse at the head of these homes there must be a period when either he or she would disapprove of the methods adopted in the Christian Science homes. Those homes did not take maternity cases, cases requiring surgical operations, or cases of infectious disease. There were at present 30 or 40 of these homes in England and Wales. If they could not obtain exemption under the Bill the result would be that Christian Scientists would be subjected to an intolerable amount of persecution merely for their religious convictions. The only other alternative was that these homes should be closed. No attempt was made under this new clause to evade any of the rules and regulations in regard to ventilation, sanitation, or such

matters. These homes were prepared to submit to any degree of inspection and registration desired by the Ministry of Health, and he understood that the new clause conformed in every way with the requirements of that Department.

Viscountess ASTOR seconded the new clause.

Sir CYRIL COBB, speaking as a member of the Select Committee, said he thought the new clause raised some difficulty. The main object that the Select Committee had before it, and which was embodied in the Bill, was to ensure that in all institutions which professed to be nursing homes there should be qualified nursing service for the public. They were not willing to make any exemptions whatever except those contained in Clause 6 of the Bill, and those were cases where people were in institutions of the nature of nursing homes for which they did not pay. They had among others cases of medical men who kept nursing homes where they received patients for fees, and a very great deal of evidence was given and pressure brought to bear upon the Committee to induce them to make a recommendation that in all cases where nursing homes were run by a medical man for gain there should be an exemption from the provisions of the Bill. They were told that the General Medical Council would ensure that such homes were properly run and provided with qualified nurses. The evidence, however, which came before the Committee showed that some of the very worse cases of neglect occurred in these nursing homes run by doctors, and the Committee found it quite impossible to make any recommendation for the exemption of such homes. The House was not dealing with a religious question at all, but with a medical question involving the protection of the public, and they should be very chary of making an exemption in the case of this particular religious body which wished to conduct treatment in homes of a special character entirely and absolutely distinct from what was generally known as nursing treatment. They had defined in the Bill what a qualified nurse was, and had provided throughout that qualified nurses were to be employed in these homes. The only relaxation of these rules was in connexion with nursing homes in existence at the present moment, and which would be carried on under regulations made by the local authorities. A certain amount of time was allowed to such homes in which to get a better staff, but in all other cases the Committee felt that no exception should be made. Therefore it was extremely difficult for him as a member of the Select Committee to agree to this clause. He must vote against it, although he did not do so with any idea of injuring a particular religious body.

Mr. MORRIS said if people believed that exemption should be granted why did they say that only permissive power to exempt should be granted to the Ministry of Health? It seemed to him to indicate that the supporters of the clause had no clear belief in their own case. Another objection he had to the clause was that it was taking the Minister of Health away from his proper duties and turning him into a theological expert. Why should the Minister of Health be the High Priest of the Christian Science Church and see that their homes were properly conducted? By allowing the name of Christian Science nursing home they were opening a new loophole. Many homes might adopt that name, and how were they to prove that people were qualified Christian Scientists? He hoped that the clause would be defeated.

Sir RICHARD LUCE said that as a member of the Select Committee he opposed the clause for several reasons. The evidence before the Committee made it perfectly evident that it was not wise to grant exemption to homes run by medical men. It would therefore be very unfair that an exemption should be given to any other body. The mover of the clause had stated there were something like 30 or 40 Christian Science nursing homes in the country. That was not at all in accordance with the evidence given to the Committee by the representative of the Church. At that time he said that there were only three Christian Science nursing homes in the country, but there were other places where patients could go to receive treatment which could not in any way be called nursing homes. He said they were a kind of boarding-house. There had either been an enormous growth in the number of Christian Science nursing homes during the last year, or else the boarding-houses were now being included. If the great majority of those homes were such as need not come under the name of "nursing home" there would be no very great hardship in closing down the few that were definitely nursing homes. But if they were really to become nursing homes there would undoubtedly be control over them to see that they kept up to the standard exacted in the case of other nursing homes. Under this clause there seemed to be no proper guarantee that the homes which were to be exempted under it would be properly inspected. The Minister did not take the responsibility of inspecting them. The evidence before the Committee was that there was absolutely no body which controlled these homes in any way. In fact, the representative of the Central Body knew extraordinarily little about the homes at all. He said that it might be possible to set up a central body to control the homes under directions from Boston, but at the time there was no such body in existence. That was a very nebulous state of affairs. There were many other methods of treatment in vogue in this country besides those of orthodox Christian Science. What was there to prevent in the case of any of those other methods the setting up of homes, and if this exemption was given how could any Minister of Health justly claim to refuse exemption in those cases also? It seemed to him that they were setting up a very dangerous precedent which would be very difficult to resist in the future. He hoped the House would not agree to the clause.

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said he was not a Christian Scientist and he did not profess even to know what were the tenets of Christian Science, but so far as it was the practice of Christian Science to substitute for medical and surgical skill some other methods he entirely disapproved of it. But he wished to ask the House to consider what would be the effect of rejecting the clause and consequently bringing institutions carried on by Christian Scientists under the provisions of the Bill. They were not concerned with the doctrines of Christian Science; what they were concerned with in this Bill was to see that no member of the public was deceived into entering one of these institutions under the impression that it was a nursing home in the sense in which that term was generally used. Christian Science was not carried on as medical treatment; it was not a species of quackery which pretended to be something that it was not. They might agree or they might not agree with it, but there was no pretence that Christian Science treatment was an alternative to medical treatment or was a variety of medical treatment. Without some form of exemption there was little doubt that these homes would come within the provisions of the Bill and be required as a condition of continued existence to appoint a qualified nurse to be resident in the home as its superintendent. But to do so would be contrary to their beliefs. It would be a case of camouflage and the result would be to do the very thing some of his hon. friends wanted to prevent. They would be deceiving or likely to deceive the public. On that account he suggested to hon. Members who were alarmed at these things that they were unwise to attempt to bring these homes within the provisions of the Bill. If such a home refused to appoint a qualified nurse it would be closed. Could they contemplate the possibility of doing that?

Dr. VERNON DAVIES said that the Bill referred to homes which were nursing homes. If the Christian Scientists referred to their homes as homes of rest or homes of treatment they would not come under the Bill at all and would not deceive the public.

Mr. CHAMBERLAIN said that was not a matter which a layman could decide; it was a legal question. It all depended whether institutions of the kind which they were discussing would come within the definition of nursing homes in the Bill, and he was advised that they would. Unless persons who desired Christian Science treatment could obtain it in their own homes it seemed to him that there would be great force in the argument of Captain Cazalet that this would be regarded as a piece of religious persecution. These were the considerations which had led him to think that the inclusion of these institutions under the provisions of the Bill offered difficulties so serious that he could not contemplate it with complacency. He had therefore to consider what was the other alternative, and in doing that he had had in mind the only consideration which concerned him—namely, the protection of the public. Provided that it was possible to isolate these particular institutions, separating them from such homes as might be set up by unqualified persons posing as medical practitioners; provided that one could get some test by which they could be separated, and could ensure that they could not call themselves by a title which would give rise to misunderstanding; and if one could also provide a safeguard so that on any change taking place in the situation an exemption could be withdrawn, then the objects which he had in view could be secured. He thought that with one exception the clause moved by Captain Cazalet carried out his (Mr. Chamberlain's) ideas. He agreed with Sir Cyril Cobb in his protest against the exemption of any kind of nursing home; but the whole point was that the Christian Science homes were not nursing homes. It seemed to him that the weak point of the clause as it stood was that they were still to be called nursing homes and he would suggest to the mover of the clause that he should use some other title which would separate those institutions entirely from nursing homes and afford no excuse to anyone to sa that he had gone there under a misapprehension. He thought that they might be called "Christian Science Houses," a term which did not involve any suggestion of medical practice.

Captain CAZALET said that he had put down the clause in its present form because they were informed that that was the best way. They were willing to take any name to effect their purpose which the Minister might suggest and which would be agreeable to the House.

Mrs. PHILIPSON said that she thought that a great difficulty would be removed if the suggestion of the Minister was adopted. She was anxious, not only from the point of view of the medical and nursing professions, but also from the point of view of the public, that all these homes should be registered and be under the control of the Minister of Health. She had been told by the chairman of the Christian Science Church that the members of that Church were perfectly willing that their homes should be registered, and if that course was taken there would be no loophole for anyone to set up a nursing home for any other purpose. She hoped that the mover and seconder of the clause would not insist upon any course which would jeopardise the passing of the Bill.

Lieut.-Colonel FREMANTLE said that he would accept the new clause at once if he had simply to consider the question of helping the work of Christian Science nursing homes so far as they were relieving people and so far as this question was concerned with liberty of conscience and freedom of experiments. But he hoped the House would recognise how grave was the position of medical men in being called upon to make such an exemption. What they were concerned with was the protection of the public. He had nothing to say against these particular homes and he knew nothing about them. The Minister of Health knew nothing about them, and the House had not been informed in that respect. They were being asked to give a blank cheque not only to these homes but to any others who came along with the same credentials. He understood that there was no body in this country representing the Christian Science faith which could certify these homes. If the Christian Science movement had been able to increase the number of its nursing home from 3 to 37 in 12 months what was to prevent them going ahead at the same rate? These places would be well equipped because they belonged to an affluent community. They would attract people who had diseases and it would become practically impossible to know whether they were nursing homes or not. The more ignorant portion of the public did not know the difference between Christian Science and any other science, and he was afraid that this would be opening the door to wide deception of the public. If they opened the door to this extent how could they prevent it being opened to say the much older and more widespread cult of homœopathy? Yet the proposed new clause did not provide for any such exemption. It would be the same with the osteopaths. The proposed exemption seemed to him most dangerous. He would like to know whether the Minister and his officers would have the right of inspection. If so, should that not be put into the clause? Personally he could not vote for the clause unless they had some definite understanding of how it was going to be carried out and how the position stood in relation to the safety of the public.

Mr. G. HURST said that he had intended to oppose the clause, but the concession which had been made by the mover seemed to him to remove all the suspicions and distrust which its opponents entertained.

Mr. C. EDWARDS said that he was very suspicious of people holding these peculiar ideas and he thought that if any registration or control was necessary in nursing homes or anywhere else it was also necessary in homes carried on by these peculiar people. Unless these places could be placed altogether outside the category of nursing homes he thought the House ought not to agree to the clause.

Dr. VERNON DAVIES said that he was grateful to the Minister for the suggestion he had made because he thought that the alterations of the words "nursing home" to "house" got over a very great deal of difficulty. Although he spoke as a medical man he could not associate himself fully with the speech of Lieut.-Colonel Fremantle. They had to recognise in this country that people had a right to their own opinions, and if they were adults they had a right to do what they liked with their lives. If a certain section of people in this country believed that the principles of Christian Science were such that they could get a better effect from them than from the ordinary medical and surgical skill that was available they had a perfect right to hold and act upon that view; and if it was necessary that homes or houses should be provided for that particular kind of treatment they had a right to go into them. Neither medical men nor Members of Parliament had a right to interfere provided they were assured that the public were safeguarded and were not deceived. Whether such persons when they got into these homes would be well or ill treated was not the concern of the community; they had gone there of their own free will. He thought, therefore, that the House could with safety accept the new clause subject to redrafting. He would suggest, however, that the Minister of Health should require that the head of the Christian Science religion in this country should actually certify that a particular place was one of their houses carried on according to their principles and thus place the onus on him.

Sir KINGSLEY WOOD said that the head of the Church would give that certificate. He suggested that they should insert in the second paragraph the word "house," and he would undertake that before the Bill reached the House of Lords the question of using some other word such as "institution" would be considered.

The clause was read a second time.

On the motion of Captain CAZALET the words "nursing home" were deleted from the clause and the word "house" was inserted.

The clause as amended was added to the Bill.

Mr. G. HURST moved an amendment to Clause 5 (Inspection of Nursing Homes) with the object of emphasising to those who had to administer the Act, that when a medical officer of health deputes some officer to visit and inspect these nursing homes he should bear in mind that the official primarily qualified to deal with questions of nursing was a qualified nurse.

Miss WILKINSON seconded the amendment which was agreed to.

Mr. CHAMBERLAIN moved amendments to Clause 8 to provide that the council of every county as respects that county and the council of every county borough as respects that borough shall be the local supervising authority under the Act; and authorising a county council to delegate to a district council any of its powers under the Bill.

The amendments were agreed to and the Bill was afterwards read a third time.

HOUSE OF LORDS.

FRIDAY, DEC. 16TH.

MENTAL DEFICIENCY BILL.

The Mental Deficiency Bill was read a second time on the motion of Viscount GAGE.

LANDLORD AND TENANT BILL.

The Landlord and Tenant No. 2 Bill was considered on Report.

On Clause 17 (which deals with the holdings to which Part 1 of the Bill applies),

The Duke of NORTHUMBERLAND moved to insert at the end of Subsection 3 the words: "A profession for the purpose of this section means the habitual and regular practice of a learned or skilled profession as the chief means of livelihood." He said that unless the word "profession" had a definite meaning in law, owners of house property could not possibly know where they stood under this Bill or what obligations or commitments they might incur. Surely the object of adding professions to businesses and trades was that the Act should apply to those learned and scientific professions which were absolutely essential to an civilised society—namely, lawyers, solicitors, doctors, dentists, surveyors, and so forth. He was not necessarily wedded to this particular definition, and if the Lord Chancellor was prepared to consider the possibility of a better definition than the one he had suggested he would be very happy to accept it.

Viscount SUMNER supported the amendment. He thought it was essential that there should be some attempt at a definition and the difficulties which were not inconsiderable should not deter them from making such attempt. If one could be sure what the policy was which underlay these words in the Bill it would be much easier to say what profession within the scope of that scheme was meant to be. As the matter stood it appeared to him that in every case it would be a question of fact whether or no premises were used for carrying on a profession. It would be a question of the user of the premises. He thought that the person who used X rays and produced an ambiguous and unattractive picture of a patient's abdomen was a very good instance. He was a person whom no one, he thought, would regard as a tradesman, and he did not think that they could call him a business man. But if he belonged to a profession, what profession did he belong to? There were other cases that could be suggested without difficulty and they amounted to quite a considerable number, particularly in large cities. In default of a better the amendment of the noble Duke was one which he would cordially support. It would be an improvement to the clause on the plain and simple ground that it would tend to reduce the number of disputes.

The LORD CHANCELLOR said that the Bill prima facie applied to premises used for trade, but the same difficulties might occur in regard to premises used for professions

r instance, there was the case of a doctor who wanted add a surgery to his house. Surely it was reasonable at if it was desired to make an improvement of that nd, and if at the end of the term some value remained the landlord, the tenant should have compensation for e unexhausted value of the improvement. The profes-nal man had no right in respect of goodwill, because the odwill of a profession was personal goodwill and was in sense attaching to the property. The noble Duke wanted go through the perilous process of defining the word rofession." What profession was not learned or skilled ? believed that those words would raise rather difficult ints for determination. The amendment also proposed provide that the profession must be carried on as the ief means of livelihood. Were they to inquire whether doctor or other professional person had means of his n on which he partly or perhaps mainly subsisted ? At outset it might be that he got very little profit from profession and might have to rely on his private income. re they for that reason to cut him off from compensation having found the money for a surgery and so forth he sequently left it ? It seemed to him that that would not only dangerous but unfair. The other qualification s that it must be " habitual and regular practice." There had some sympathy with the noble Duke, and would e to meet him. If he agreed and was prepared to with-w his amendment he (the Lord Chancellor) would move insert in the proviso in Subsection 3 the word " regu-ly."

The Duke of NORTHUMBERLAND withdrew his amendment l the Lord Chancellor's suggested amendment was eed to.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 14TH.

Sickness and Mortality among Troops in China.

Mr. TREVELYAN asked the Secretary of State for War what the statistics of sickness and mortality had been in British force in China in the months of July, August, tember, October, and November; and (2) what the istics of sickness and mortality had been in the British e at Shanghai in the months of July, August, September, ober, and November.—Commodore DOUGLAS KING nancial Secretary to the War Office) replied: The infor-ion is as follows: 1. Approximate average number in pital at Hong Kong, Shanghai, Tientsin, Pekin, and i-hai-Wei :—

Month.	Officers.	Other ranks.
uly	39	1309
ugust	25	1132

(*a*) Includes one officer.

Loss of Working Days through Sickness.

r. SMEDLEY CROOKE asked the Minister of Health the of working days caused by sickness during the years and 1926.—Mr. CHAMBERLAIN replied: There are no available as regards the general population. As ds persons insured under the National Health Insurance (some 14,000,000 in England and Wales), it has been mated by reference to the sums paid by way of sickness disablement benefit under the Act, that the time lost ickness in England and Wales was :—During 1925 rds of 150,000,000 working days; during 1926 upwards 39,000,000 working days. In making these estimates nt has to be taken of a number of uncertain rs, and the result can only be regarded as a rough oximation.

THURSDAY, DEC. 15TH.

Dangers in the Use of Acetylene Plant.

. GIBBINS asked the Home Secretary whether his atten-had been called to the recent fatal accident whereby two boilermakers using an acetylene burner were gassed and burnt to death inside the tank of a ship in Clarence Dock, Liverpool; and if he would consider whether special regulations are needed to minimise the dangers caused by the use of mechanical appliances in confined spaces.—Sir WILLIAM JOYNSON-HICKS replied: The circumstances of this accident were exceptional. It was due to the men having blown a large quantity of oxygen into the confined space of the tank for the purpose of removing some smoke which had accumulated there from a smouldering sack and having then entered the tank with a lighted candle. The accident was not connected in any way with the use of acetylene plant, but I may say that the danger from fumes or gas in connexion with such plant is fully recognised and special precautions against it are proposed in the draft new Shipbuilding Regulations.

Small-pox at Newcastle Workhouse.

Mr. GROVES asked the Minister of Health how many cases of small-pox had been reported from the workhouse at Newcastle-on-Tyne; how many of them had been vaccinated or revaccinated; when was the last general revaccination of the inmates prior to this outbreak; and whether any inmates recently vaccinated or revaccinated who were attacked by small-pox were suffering from any other disease at the time of the attack.—Mr. CHAMBERLAIN replied: Forty-five cases of small-pox have recently occurred in the Newcastle-on-Tyne Poor-law Institution. Forty-two of these cases had, at the time of infection by small-pox, been vaccinated in infancy only, and their ages ranged from 17 to 70 years. In addition, one had been revaccinated ten years ago. Prior to the present outbreak there has been no general revaccination of the inmates during the past 15 years. The answer to the last part of the question is in the affirmative, but in none of these cases was the vaccination successful.

Municipal Sunlight and Vapour Baths.

Lieut.-Commander KENWORTHY asked the Minister o Health whether his attention had been called to the succes: of the recently opened sunlight and vapour baths of the Hull Corporation; and whether he would recommend a similar system to other municipalities.—Mr. CHAMBERLAIN replied: I am aware of the establishment referred to, and recently paid a visit to it myself. While I regard the Hull baths as an interesting and valuable experiment, I do not think it has been long enough in existence to justify the somewhat unusual step proposed.

Mr. GROTRIAN: Will the right hon. gentleman take care that these baths are not instituted except under proper expert advice and management ?—Mr. CHAMBERLAIN: I do not think there is any deficiency in that respect.

Lieut.-Commander KENWORTHY: Is the right hon. gentleman aware that the chairman of the Baths Committee is a senior medical practitioner ?—Mr. Chamberlain: I do not think there is any reflection to be made on these baths.

Lay Practitioners and Electrical Treatment.

Mr. HARDIE asked the Minister of Health whether he would take steps to obtain powers of control over lay establishments for treatment by ultra-violet and other radiations.—Mr. CHAMBERLAIN replied: The object sought in the question could only be obtained by legislation, and I am not, as at present advised, prepared to introduce legislation for the purpose.

Scientific Societies and Income-tax.

Mr. CLAYTON asked the Chancellor of the Exchequer whether he was aware that, pending the decision of certain cases before the High Court, the return of income-tax to certain scientific societies hitherto regarded as charitable institutions was being withheld; and, as such action, especially in the cases of those societies which have annually to distribute funds for research purposes, was a hardship and one which must necessarily curtail research work carried out in universities and university institutions, would he arrange to have these taxes refunded.—Mr. CHURCHILL replied: Appeals in the High Court are pending against decisions of the Special Commissioners of Income-tax holding that two societies were not entitled to exemption from income-tax as charities. These two societies, after discussion between representatives of a large group of learned and scientific societies and the revenue authorities, had been taken as test cases. Unless these decisions of the Special Commissioners on appeal are reversed by the courts, it would not be possible for the Inland Revenue to continue to make repayments of tax in respect of income of the general funds of other societies of the same character. If, however, my hon. friend is aware of any cases in which relief has not been admitted in respect of income which is subject to a specific trust for application to research in a university or university institution, I shall gladly make

further inquiry on being furnished with the necessary particulars.

MONDAY, DEC. 19TH.

Public Hospital Accommodation in India.

Mr. SCURR asked the Under Secretary of State for India whether any information was available as to the provision of public hospital accommodation in British India in relation to the needs of the population.—Earl WINTERTON replied: The latest information available relates to the year 1925. The total number of State, public, local, and private aided hospitals and dispensaries in British India in that year was 3972, and the number of beds available 45,049. The numbers of indoor and outdoor patients treated were 738,570 and 4 0,472,780 respectively.

Women's Hospitals in India.

Mr. SCURR asked the Under Secretary of State for India how many women's hospitals existed in British India both for maternity and general cases.—Earl WINTERTON replied: The total number of female hospitals and dispensaries in British India recorded in the official reports for 1925 was 173 with 4249 beds available. The number of beds available for women in general hospitals was 11,260.

The Services.

COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

A LIMITED number of commissions in the Royal Army Medical Corps, not exceeding 25, will be offered in January next. Applications for consideration should reach the Under Secretary of State, War Office (A.M.D.I.), Whitehall, London, S.W. 1, not later than Jan. 10th, 1928. There will be no entrance examination.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capts.: J. H. Fergusson to *Egmont* for hospital ship *Maine*; and W. W. Keir to *Tamar* for R.N. Hospl., Hong-Kong.

Surg. Comdrs.: H. M. Whelan to *Egmont* for hospital ship *Maine*; T. Creaser to *Hood*, and as squadron medical officer; G. D. Walsh to *Revenge*; B. R. Bickford to *Iron Duke*, as squadron medical officer and as specialist in ophthalmology; T. W. Jeffery to *Nelson*, and as fleet medical officer; F. J. D. Twigg to *Victory*, for Haslar Hospl., and as specialist in ophthalmology; A. R. Schofield to *Vernon*; G. H. Hayes to *President*, for six months' post-graduate course; H. H. Ormsby to *Dartmouth*; G. A. S. Hamilton to *Tiger*; and H. E. Perkins to *Osprey*.

Surg. Lt.-Comdrs.: B. S. Collings to *Nelson*; J. F. Ainley to *Victory*, for R.N. Barracks; and G. E. Heath to *President*, for three months' post-graduate course.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Capt. W. K. Wills is placed on the Ret. List.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. S. B. Smith, having attained the age fixed for compulsory retirement, retires on ret. pay.

Maj. J. H. Campbell to be Lt.-Col., vice Lt.-Col. S. B. Smith to ret. pay.

Temp. Lt. A. Nicolson relinquishes his commn.

D. W. Stuart to be Temp. Lt.

ARMY DENTAL CORPS.

Lts. to be Capts.: J. B. Cowie, R. E. Edwards, and F. S. S. Whiter (Temp. Flying Officer, R.A.F.).

TERRITORIAL ARMY.

Maj. G. E. J. A. Robinson, having attained the age limit, is ret. and retains his rank, with permission to wear the prescribed uniform.

ROYAL AIR FORCE.

Flight Lt. E. A. Wheeler (temporary Major, Dental Surgeon, General List) is promoted to the rank of Honorary Squadron Leader.

DUNDEE ROYAL INFIRMARY.—The directors of this institution have received notification that the trustees of the late Sir James Duncan have set aside £30,000 for the Infirmary out of the residue of the estate.

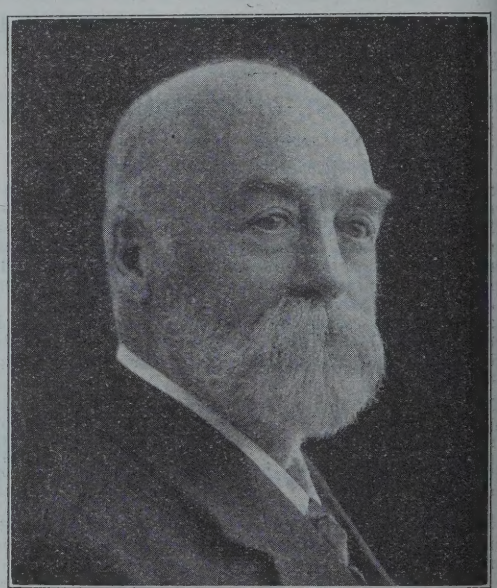
Obituary.

AMAND McCONNEL ROUTH, M.D., B.S., F.R.C.P. LOND.,

CONSULTING OBSTETRIC PHYSICIAN TO CHARING CROSS HOSPITAL.

WE regret to announce the death of Dr. Amand Routh, the well-known obstetric physician, which occurred at his country house, Grimston Court, near Folkestone, on Dec. 18th, in the seventy-fourth year of his age.

Amand Jules McConnel Routh, son of the late Dr. C. H. F. Routh, whose work and writing in the same sphere as that of his son were prominent in their day, was born in 1853, and received his early education at King's College School. Later he joined the medical school of University College Hospital. Having taken the double diploma of the English colleges he graduated in medicine at London University in 1881, proceeding to the doctorate in the following year, when he also took the M.R.C.P.



DR. AMAND ROUTH.

He was promptly elected physician to the Marylebone Infirmary and was also appointed anæsthetist at the Samaritan Free Hospital for Women, where his father was a member of the medical staff and where he also became out-patient physician; but in 1883 he was elected obstetric physician to Charing Cross Hospital, a post which he held for 30 years. He remained on the staff of the Samaritan Hospital also until 1901, and his distinguished career in his specialty justified the early openings thus offered him, for his work here and at Charing Cross Hospital advanced him to a leading position in gynæcology and obstetrics not only in London but throughout Europe. The staff at Charing Cross were at this time reinforced by four distinguished recruits from University College, and Routh was their last survivor—the others being Frederick Mott, Stanley Boyd, and Montague Murphy—and at the hospital rules were abrogated at once in Routh's favour, whereby abdominal operations, unless upon a pregnant patient, were performed by a surgeon of the hospital and not by the obstetric physician. Routh made admirable use of the opportunities thus afforded, for he became known as a skilful surgeon along the many lines thus opened up. The professional confidence reposed in him was shown by his selection by

English Royal Colleges to represent them at the Fifth International Congress of Obstetrics and Gynæcology held in St. Petersburg in September, 1910. His report dealt with Cæsarean section in Great Britain and Ireland, and included tables of 1282 cases of the operation as performed by over 100 living operators. At this date extra-peritoneal Cæsarean section was of recent introduction, and the subject was much discussed both on its merits as an operation and in reference to the conditions of its performance, there being no common agreement as to how far an answer had been supplied to the difficult question—what is the correct treatment to adopt in the case of women with contracted pelves, who are in labour, and who are possibly or probably already infected? Routh's report formed the subject of a debate which he himself opened at a meeting of the Section of the Royal Society of Medicine, and although there was no general endorsement of his views, he was allowed to have helped greatly in indicating the difficulties. The discussion proved that in clean and suitable cases, at dates fixed beforehand, without previous attempts at delivery, the mortality of Cæsarean section could be reduced to something like 1 per cent.

With another side of his science Routh's name will always be intimately connected—namely, antenatal pathology. An early supporter of the Council of the National Association for the Prevention of Infantile Mortality, he made a special study of the antenatal conditions and of the directions in which medical supervision might obviate disasters. He put forward his views before the Royal Society of Medicine in 1914, when he opened a debate on the subject, urging the need of research. Allowing for the essential differences in the physiological and pathological activity of the embryo and the fœtus, he pointed out that in either case disease might lead to abortion or premature labour, and he dwelt in particular on antenatal syphilis and antenatal tuberculosis as subjects that required elucidation. He was, indeed, one of the first to point out clearly that, although pregnancy is a normal process, it is one that is conducted under physiological stress and in connexion with which disturbances of a pathological nature form proper material for the earliest possible investigation. The lessons which he inculcated are now acted upon, and the importance of a regular watch over pregnancy is no longer dismissed with a few words of advice from the teachers in the schools, but periodical examinations of the pregnant woman are recognised as being the supreme way in which signs of abnormality can be studied and dealt with at a remediable stage. Until this fact became common experience antenatal care was regarded lightly; to-day it is known that there is a direct relation between the experience of the midwife as regards antenatal work and the number of medical aid notices which are sent during labour—practical proof of the value of antenatal observation. Like many pioneers Routh was supposed to be over-enthusiastic as to the merits of such observation, but any one can read the collection of essays that were brought together recently in an extra number of THE LANCET (Modern Methods in Abnormal and Difficult Labour) without seeing how steadily the estimation of antenatal care has risen in the minds of all who are concerned practically with the problems of pregnancy and labour. Repeatedly the comment is made in these essays, when dealing with the various phenomena and complications of abnormal and difficult labour, that the risks and troubles would have been precluded by antenatal care, and every hospital through its obstetric departments now takes up this attitude. Routh was a pioneer in this important work.

Routh was, also, specially interested in the association of syphilis and marriage, as the cause of more individual and social national trouble than any other disease affecting family life. The last important paper published in our columns from his pen—a communication made previously to the Society for the Study of Venereal Disease—dealt with this subject at length, and showed how long it had been under his consideration. Five years previously he had drawn attention in our columns to the probability that during pregnancy the treatment of a congenitally syphilitic child if properly undertaken is attended with remarkable success, whereas treatment of the same children begun only after birth will be given at a time when the latent period is over and is apt to prove unsatisfactory. His later communication justified his premises.

To return to Amand Routh's official career, he joined the original Obstetrical Society of London immediately after graduation, was elected F.R.C.P. in 1900, and became in due course a member of the council of the Society, librarian, secretary, and vice-president; in 1911, after the incorporation of the old Society with the Royal Society of Medicine, he was made President of the Section of Obstetrics and Gynæcology. Here his introductory and retiring presidential addresses struck a modern note, for he pointed out the need for advance in biological research as regards chemical, physiological, and pathological problems involved in the processes of menstruation, labour, lactation, and also the toxæmias of pregnancy. When President of the Harveian Society, as in the proceedings before the Royal Society of Medicine, he made valuable observations upon antenatal syphilis and the results of latent syphilis during pregnancy, offering suggestions which have since been confirmed in many directions. He was much in request as an examiner, discharging these functions at the English Conjoint Board, and also at the Universities of London, Birmingham, and Cambridge. In the University of London he was a member of the Standing Committee of Convocation for some 20 years—that is, until his retirement in 1923, and for a long portion of this period he sat on the Board of Advanced Medical Studies.

Routh was a prominent member of the Church of England, and was churchwarden at St. Paul's, Portman-square, for nearly 20 years; no doubt his religious feelings played a part in his attitude towards artificial birth control, save under medical advice, and many of similar views to his own found his arguments for the spacing of the arrival of children by self-control and abstinence to be a satisfactory substitute for mechanical methods of contraception. He was also a prominent Freemason, and after retirement to Folkestone became prominently associated with the civil activities of the borough. In his youth he had been a successful athlete, and until late middle life was an enthusiastic golfer.

This, it will be seen, is a record of a long life spent not only in intensive investigations along special lines but in bringing the resulting work into relation with all medicine and all society.

RINGER SOCIETY: THE ANNUAL DINNER.—The first annual dinner of this society was held on Dec. 10th at Jules Restaurant. The President, Dr. Henry Ellis, took the chair, and in the presence of a large company of guests delivered the Ringer oration. He explained that the society was named after Sydney Ringer, one of the first clinicians to realise the value of physiology and biochemistry applied to practical medicine, and perhaps best remembered by his perfusion experiments with the fluid which bore his name. The council of the society, said the President, had been actively engaged in formulating standards of urinary analysis, and these were almost complete. In the coming year the society would proceed to define standards for blood in the same way. Prof. Hugh MacLean, in response to the toast of Clinical Biochemistry, said he was much interested in the evidence presented of the activities of the new society. The health of the guests was proposed by Dr. Halls Dally, and Prof. Joseph Barcroft responded. Prof. F. G. Hobday, in thanking the society for its hospitality, said that he was confident that the coöperation of veterinarians would be very useful. Animals could be most advantageously used in the study of the effects of diet on metabolism. Dr. Langdon Brown and Dr. C. M. Wilson also replied and expressed optimism about the future of biochemistry applied clinically in the way advocated by the society. The health of the President was proposed by Dr. David Barcroft.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on Dec. 17th the following degrees were conferred :—

D.M.—Sibyl Eastwood.

B.M.—H. A. Byworth, L. W. H. Bertie, H. P. Gilding, A. W. Cubitt, A. P. Kingsley, and R. E. Havard.

The Francis Gotch Memorial Prize in Physiology has been awarded to Mr. John Carew Eccles, M.B., who has also been elected to a Junior Research Fellowship at Exeter College. Dr. Eccles, who is a Rhodes Scholar from the University of Melbourne, obtained a first class in the Honour School of Physiology and was elected Christopher Welch Scholar in Biology this year.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Dec. 10th the following degrees were conferred :—

M.B. and B.Chir.—I. A. Jackson, B. W. S. Mackenzie, and W. E. Chiesman.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on Dec. 14th the title of emeritus professor of pathology was conferred on Sir Frederick Andrewes, F.R.S., who, in July, 1927, retired from the University professorship of pathology tenable at St. Bartholomew's Hospital Medical College. The degree of D.Sc. has been conferred on Mr. F. C. Minett for a thesis on the Standardisation of Immune Serum and the Nature of Immunity in Foot-and-Mouth Disease, and other papers. Lord Dawson was appointed as the University's representative at the tercentenary celebrations in honour of William Harvey, patron of the Royal College of Physicians, to be held in May, 1928.

At examinations held recently the following candidates were successful :—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Honours.—Russell C. Brock (*a*, *d*), Nils L. B. V. Eckhoff (*d*), and Arthur B. Hyman (*b*), Guy's Hosp. ; Robin S. Pilcher (*a*, *d*, *e*, University Medal), Univ. Coll. Hosp. ; Kenneth H. Watkins (*a*, *d*), Univ. of Manchester.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

Pass.—Chandumal A. Amesur, St. Thomas's Hosp. ; Vernon F. Anderson, Westminster Hosp. ; William A. Ball, King's Coll. Hosp. ; Benjamin Barling, Univ. Coll. Hosp. ; Philip Berry and Lascelles R. B. Birt, Guy's Hosp. ; James W. Bottoms, London Hosp. ; Roger V. Bowles, Univ. Coll. Hosp. ; Frank W. Bradley, Guy's Hosp. ; Doris E. Bunbury, London Sch. of Med. for Women ; Maurice R. Burke, St. George's Hosp. ; Isabella M. G. Butler, Univ. Coll. Hosp. ; John C. D. Carothers, St. Thomas's Hosp. ; Phyllys P. Case, Charing Cross Hosp. ; John A. Cholmeley, St. Bart.'s Hosp. ; Maneckjee M. Cowasjee, Guy's Hosp., Frank H. N. Cruchley, London Hosp. ; Rupert P. P. Davies, St. George's Hosp. ; Douglas A. Dewhirst, St. Bart.'s Hosp. ; Hugh A. Dunlop, Westminster Hosp. ; Phyllis M. Edgar, Univ. Coll. Hosp. ; Donald C. McC. Ettles, Guy's Hosp. ; Libero Fatti, Univ. Coll. Hosp. ; Roy R. Fells and James R. Forrest, St. Bart.'s Hosp. ; Isabella Forshall, London Sch. of Med. for Women ; Krishnalal T. Gajjar, Univ. Coll. Hosp. ; Helena M. Gambrell, London Sch. of Med. for Women ; Dorothy Godden, London Sch. of Med. for Women and St. Mary's Hosp. ; Abraham Golombek, King's Coll. Hosp. ; Helen R. Goodman, London Sch. of Med. for Women ; Sydney W. Hardwick and Gwilym E. Harries, St. Bart.'s Hosp. ; Catherine M. Hext, London Hosp. ; Sydney L. Hicks ; Univ. Coll. Hosp. ; John W. O. Holmes, St. Bart.'s Hosp. ; Isabel E. S. James and Arthur W. Kendall, King's Coll. Hosp. ; Ambrose J. King, London Hosp. ; Eileen M. King, Univ. Coll. Hosp. ; John G. Kingsbury, Guy's Hosp. ; Caroline M. Kingsmill, London Sch. of Med. for Women and St. Mary's Hosp. ; Frank E. Kingston, London Hosp. ; Kenneth H. Lachlan, Westminster Hosp. ; Richard A. V. Lewys-Lloyd, St. Bart.'s Hosp. ; Isabella L. H. Livingstone, King's Coll. Hosp. ; Lewis J. McGregor, St. Thomas's Hosp. ; Robert M. Maher, Univ. of Liverpool ; Hugh L. Marriott, Middlesex Hosp. ; Swithin P. Meadows, Univ. of Liverpool ; Roy L. Midgley, Univ. Coll. Hosp. ; William S. Morgan, St. Bart.'s Hosp. ; Leonard Moss and Mark A. Nicholson, London Hosp. ; William D. Nicol, St. Bart.'s Hosp. ; Ethel E. M. Ogilvie, London Sch. of Med. for Women ; Nathoobhai D. Patel, Univ. Coll. Hosp. ; Reginald T. Payne, St. Bart.'s Hosp. ; Kudatelagé R. T. Peiris, King's Coll. Hosp. ; Ethel E. A. Pepper, London Sch. of Med. for Women ; Gangadhar M. Phadke, Univ. Coll. Hosp. ; Leonard G. J. Pitt-Payne, Guy's Hosp. ; Max M. Posel and Evan R. Rees, St. Bart.'s Hosp. ; Elsie E. A. Ridley, London Sch. of Med. for Women ; Muriel Rippin, Univ. Coll. Hosp. ; Edward H. Roche, Guy's Hosp. ; James E. C. Rouse, St. George's Hosp. ; Brian F. Russell, London Hosp. ; Margaret V. Saul, King's Coll. Hosp. ; William D. Sheldrake, Guy's Hosp. ; Eric W. Skipper, London Hosp. ; Hilda W. Slack, London Sch. of Med. for Women ; William R. C. Spicer, Guy's Hosp. ; Olive F. Sydenham, Univ. of Birmingham ; Victoria W. Symonds and Dorothy Taylor, St. Mary's Hosp. ; Kathleen A. Vernon, London Sch. of Med. for Women ; Richard F. Ward, London Hosp. ; John G. Weston, Guy's Hosp. ; Dorothy M. Wilkins, London Sch. of Med. for Women ; Michael C. Wilkinson, St. Thomas's Hosp. ; John E. B. Williams, Univ. Coll. Hosp. ; Elsie B. Wright, London Sch. of Med. for Women ; and Harry D. Wyse, Guy's Hosp.

UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates were successful :—

Final M.B., Ch.B.—R. S. Abraham, S. K. Appleton, Soloman Bernstein, Agnes N. Buckley, Eric Cretney, E. B. Davies, D. E. Francis, Dorothy Guest, Amy H. Herbert, G. D. Hithersay, J. H. Jones, James Kemp, Kathleen McGowan, Jean McD. Marshall, H. E. Martin, J. R. Nuttall, Nora Ridehalgh, Lucy Stokoe, C. E. Sykes, and Joseph Vine.

Forensic Medicine.—E. H. Brooks and J. A. Longworth.

Hygiene and Preventive Medicine.—Doris Bernard, E. H. Brooks, Mary G. Davies, G. B. Hardman, E. P. Johnson, J. A. Longworth, and J. W. Murray.

Obstetrics and Surgery.—G. L. Brown, D. E. Francis, Alexandra W. Groves, I. M. Hughes, Morris Levine, Kathleen McGowan, J. S. Miller, E. J. B. Sewell, Henry Tickle, and J. F. Wilkinson.

Obstetrics.—Stanley Nowell.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial held on Dec. 16th the following degrees and diplomas were conferred :—

M.D.—E. W. Anderson, M. J. Bett, †George Brewster, ‡J. C. B. Craig, ‡Sidney E. Croskery, †D. M. Dunlop, H. J. C. Durward, J. F. Fraser, I. M. D. Grieve, H. H. Holden, G. J. Hughes, ‡D. J. A. Kerr, *J. G. Kininmonth, Helen M. Russell, H. T. Smith, †Donald Stewart, and †David Wilkie.

Ch.M.—‡A. L. M'Gregor.

M.B., Ch.B.—C. H. B. Adamson, H. J. van den Berg, A. G. Bonnyman, K. V. R. Choudari, Bessie L. Clark, A. J. Clements, Bernard Cohen, J. L. Cowan, T. A. Edwards, E. A. Fergusson, Jessie D. Forrester, James Fraser, L. M. E. R. Henshaw, W. H. Houghton, Samuel Jesudasen, W. H. E. Johnson, F. M. Khan, Joseph Kingsley, A. A. MacArthur, J. W. B. Macdonald, A. E. Mackintosh, Kenneth M'Neill, A. G. R. Macpherson, A. W. MacQuarrie, F. F. Main, Richard Mennie, W. M. Mitchell, W. D. Moore, J. S. R. Pandit, W. H. D. Patterson, P. J. G. Payne, Frances M. Porter, L. L. Ratazzi, A. S. Reilly, R. H. Robertson, J. M. Russell, B. S. Sandhu, Margaret A. Spencer, E. R. Thomson, E. W. T. Webber, and Elisabeth M. Williams.

D.P.H.—Margaret A. Mackenzie.

* Awarded gold medal for thesis.

† Highly commended for thesis. ‡ Commended for thesis.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The College will be closed from to-day (Friday) Dec. 23rd until Saturday, Dec. 31st, both days inclusive.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.—The December meeting will not take place and the next meeting will be held on Wednesday, Jan. 25th. Sir John Bland-Sutton will deliver the Annual Oration on May 23rd, his subject being the Debt of Dermatology to Optical Glass.

ROYAL INSTITUTION OF GREAT BRITAIN.—Two lectures on the Physiological Aspects of Flying will be delivered by Group-Captain Martin Flack, Director of Medical Research in the Royal Air Force Medical Service, at 5.15 P.M. on Thursdays, March 22nd and 29th. On March 2nd Sir Farquhar Buzzard will give a Friday evening discourse on the Psychology of the Sick.

PORTRAIT OF THE LATE DR. ADAMI.—A portrait of the late Dr. J. G. Adami, Vice-Chancellor of the University of Liverpool, has been hung in the Assembly Hall of the medical building at McGill University, Montreal, where Dr. Adami was for many years professor of pathology. The portrait was subscribed for by Dr. Adami's many friends, pupils, and former assistants.

CHELSEA HOSPITAL FOR WOMEN.—This hospital of 97 beds is doing double its former work with no increase in the number of its voluntary supporters, and a special appeal is being made for the purchase of radium. A floor of 18 beds is reserved for patients able to pay five guineas a week and small fees to the staff for operations.

NEW RULES AT A BIRMINGHAM HOSPITAL.—The Birmingham and Midland Ear and Throat Hospital has made a rule that the honorary and assistant surgeons shall not hold an appointment at any other hospital, on the ground that duplicate appointments militate against the adequate performance of their duties. In consequence of the establishment of the hospital contributory scheme tickets for this hospital have been abolished.

BRITISH CHARITIES ASSOCIATION.—Lord Knutsford, who presided at the fourth annual meeting of the British Charities Association held at Kingsway House, W.C., on Dec. 15th, stated that the activities of the Association had resulted in a surplus for the year of £18,150, being an increase of over £4000 on the previous year's figure. Distributions to voluntary hospitals during the year amounted to £20,600 and since the close of the year the Council have made further grants of £15,000 to King Edward's Hospital Fund for London and £5000 to the League of Mercy. The total distributions since the formation of the Association four years ago now exceed £173,700. In announcing the Association's latest prize competition, consisting of a Bovril Slogan Ballot, with £6000 in prizes presented by Bovril

td., the chairman invited all voluntary hospitals to coöpe-
te by availing themselves of the offer of tickets, which the
ssociation issues, free of cost, to any voluntary hospital
r sale on behalf of its own funds.

Appointments.

YONS, LESLIE, L.D.S. R.C.S. Eng., has been appointed Clinical Assistant in the Dental Department of King's College Hospital, Denmark Hill, S.E.

ueen Charlotte's Maternity Hospital: PEIRCE, G. E. G., M.B., B.S., Senior Resident Medical Officer; ROSS, G. A., M.B., Ch.B., Assistant Resident Medical Officer.

niversity of Manchester: HILL, E. F., M.B., Ch.B. Manch., Lecturer in Anæsthetics; WRIGLEY, F. G., M.D. Manch., Lecturer in Diseases of the Throat and Nose; COOPER, E. R. A., M.D. Manch., Lecturer in Histology; HOWE, F., M.B., Ch.B. Manch., Demonstrator in Anatomy.

Vacancies.

For further information refer to the advertisement columns.

erdeen Royal Hospital for Sick Children.—Lady Supt.

erdeen Royal Infirmary.—Hon. Jun. Asst. Ophth. S.

gyle and Bute District Memorial Hospital, Lochgilphead.—Asst. M.O. £300.

rmondsey, Borough of.—Asst. M.O. for Maternity and Child Welfare. £600.

rmingham Pensions Hospitals Committee.—Jun. Surg. O. £300.

ckburn and East Lancashire Royal Infirmary.—3rd H.S. £150.

entry and Warwickshire Hospital.—Res. H.S. £125.

rby, Derbyshire Royal Infirmary.—Hon. Gynæcologist.

rham, Seaham Hall Sanatorium.—Med. Supt. £600.

ldford Union.—Res. Asst. M.O. £150.

ckney Hospital, High Street, Homerton, E.—Jun. Asst. M.O. £350.

ndon Union, Redhill Hospital, Edgware.—Res. Deputy Med. Supt. £300.

spital for Tropical Diseases, Endsleigh-gardens, W.C.—Hon. Asst. P.

ll Royal Infirmary.—Second H.S. At rate of £150.

coln, The Lawn.—Med. Supt. £700.

don School of Hygiene and Tropical Medicine, University Chair of Public Health.—£1300.

nchester Royal Infirmary, Central Branch, Roby-street.—Jun. H.S. £100.

tingham City Board of Guardians.—Dist. M.O.

thampton, Creaton Sanatorium.—Med. Supt. £550.

tingham General Hospital.—H.S. At rate of £150.

tsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.

nce of Wales's General Hospital, Tottenham, N.—Hon. Anæsthetist.

al Army Medical Corps.—Limited number of Commissions.

Paul's Hospital for Diseases of the Genito-Urinary Organs and Skin, Endell-street, W.C.—Res. M.O. At rate of £200.

field, Jessop Hospital for Women.—Two Asst. H.S.'s. At rate of £100.

efield, West Riding Mental Hospital.—Jun. Asst. M.O. £400.

esden General Hospital, Harlesden-road, N.W.—H.S. At rate of £100.

irths, Marriages, and Deaths.

BIRTHS.

IBIE.—On Dec. 10th, at Beaufort House, Ealing, the wife of Dr. Frank Crosbie, of twin sons.

LY.—On Dec. 18th, at Vernon House, Lee-road, Blackheath, the wife of Dr. Guy Neely, of a daughter.

ERS.—On Nov. 22nd, at "Lavalance" Nursing Home, Bordeaux, the wife of Oswald H. Vevers, M.R.C.S., L.R.C.P. Lond., of Villa Beaugeard, Arcachon, of a son.

MARRIAGES.

WELL—HILL.—On Dec. 17th, at St. Columba's Church, London, Dr. Robert Stevenson Caldwell, of New Milton, to Stephanie Winifred Hill.

DEATHS.

HAM.—On Dec. 14th, at Wellesley House, Cirencester, William Raymond Cossham, M.D., aged 76 years.

D.—On Dec. 9th, at Falmouth, Cornwall, Albert Frederick Field, M.D., late St. Bartholomew's Hospital, aged 83.

SWELL.—On Dec. 14th, aged 71 years, Albert Gresswell, M.A., M.D. Oxf., St. Bart.'s, of Kelsey House, Louth, Lincs.

ME.—On Dec. 14th, at Finborough, Suffolk, William Wollaston Groome, M.D., aged 74.

H.—On Dec. 18th, at his residence, Grimston Court, Folkestone, Amand Jules McConnel Routh, M.D., F.R.C.P.

—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE ROMANCE OF LONDON'S WATER-SUPPLY.

AT Islington, near the Agricultural Hall, stands a memorial to Sir Hugh Myddleton, who led pure water to London from the springs of Chadwell and Amwell, tributaries of the New River, over 300 years ago, just before Harvey discovered the circulation of the blood. Since then London's water-supply has continually expanded and improved, and every day 7 millions of citizens use on an average 37 gallons each of water which for chemical and bacterial purity is unsurpassed. One remarkable thing about the engineering marvels of the Water Board is their extreme unobtrusiveness. Both the proposer and the seconder of a vote of thanks to Sir Alexander Houston for an illuminating lecture on this subject, delivered at the Royal Society of Medicine's social evening on Dec. 14th, admitted that the bulk of what he had said had been absolutely new to them, and their ignorance must be representative of that of most of London's population. Probably few citizens could name the principal reservoirs in which their drinking-water is stored, nor enumerate the steps taken to purify it. Actually the list is so long that it would tax an ordinary memory, for there are no less than 49 storage reservoirs, with a total area of 2704 acres and a content of 19,657 millions of gallons, enough to supply London for 80 days. The Thames water is stored at Staines, Walton, Hampton, and Hammersmith, and makes up 60 per cent. of the total supply. The remainder comes from the New River, the Lea, and deep wells in the Kentish chalk.

Thames water is purified by storage, sand filtration, and chlorination, said Sir Alexander Houston, but storage alone is a most effective means of purification. Suspended matter is precipitated and organic matter is decomposed; good and bad water are mixed, to the benefit of the mixture, and undesirable bacteria lose their vitality, so that adequate storage is nearly equivalent to sterilisation. The length of time at the Chelsea reservoir is 15 days, and this reduces the colon bacillus content to one-hundredth. The chemical improvement that results from storage alone is equally striking; great reduction takes place in the turbidity and ammoniacal nitrogen content, and, in lesser degree, in the percentage of albuminoid nitrogen. A disadvantage of storage is, however, the encouragement it gives to the growth of algæ; these bodies sometimes multiply to such a formidable extent that they not only give an unpleasant taste to the water but interfere with the working of the filters. Sir Alexander Houston showed several microphotographs of these harmless but troublesome organisms, which are controlled by means of minute quantities of copper sulphate. The rate of filtration is very slow, about 2 gallons per square foot per hour, a movement equivalent to that of the point of the minute hand of a watch. The depth of water on the bed is about 4 feet, and the bed itself consists of 3 feet of fine sand, 12 inches of coarse sand, 9 inches of fine gravel, and 9 more of coarse gravel. Every two or three months the bed has to be cleaned; the water is run off and the sand collected into heaps and washed. Filtration reduces the colon bacillus content from 1000 colonies in 100 c.cm. to one each in 75 per cent. of the samples and none in the remainder.

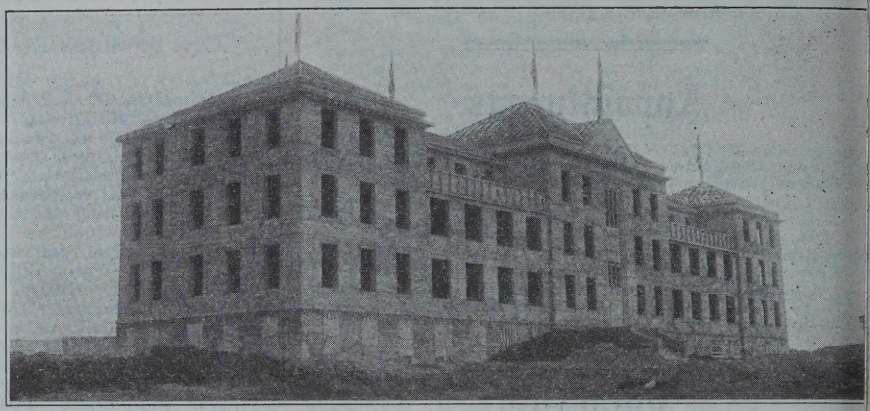
Chlorination was introduced in 1916 as a war economy, but was actually more effective in destroying bacteria than prolonged storage. Sir Alexander Houston, who was the first to use the method in this country, showed a picture of an improvised apparatus consisting of a number of earthenware jars fed by a man with a jug, and in contrast to this some of the latest models of chlorination were shown in operation in the library. The dose is very small; one-half of a part to a million for Thames water and one-quarter for Lea water. The Lea, as the lecturer reminded his audience, was the river so beloved of the great Isaak Walton. It rises near Dunstable and flows into the Thames near the East End of London, and the reservoirs at Chingford and Walthamstow hold 3000 and 2000 million gallons respectively.

Apart from the service they render Londoners in supplying unlimited fresh water, these great artificial lakes harbour innumerable rare wild fowl on the islands with which they are dotted, for no shooting is permitted over them. Sir Alexander Houston remarked that he had seen 24 heron in the air at once, startled by a gun fired on the neighbouring marshes, and ended his lecture with a splendid photograph of a great crested grebe on her nest, taken less than 5 miles from Henrietta-street.

Dr. Joseph Clarke McPherson, senior medical officer, has been appointed by the King an Official Member of the Executive Council of the Presidency of Montserrat.

A HOSPITAL IN ICELAND.

THE foundation-stone of a new national hospital at Reykjavik was laid in 1926 by the Queen of Iceland and Denmark, and the accompanying photograph, which was taken some months ago, shows the hospital with its roof completed. The flags were placed on the roof by the workmen in accordance with a national custom. As soon as the timbers are in place the proprietor of the building is expected to entertain the builders, and it is said that the flags would not be removed should he fail to do so. The hospital will be heated throughout by water from a natural hot spring.



The National Hospital, Iceland.

ABORTING VENEREAL DISEASE IN INDIA.

STATISTICS of immediate prophylactic treatment suggest that this method has value in the prevention of venereal disease, though results are far from uniform. The essentials to success appear to be conviction on the part of the responsible medical officer, detailed supervision, availability of treatment very soon after risk, and a suitable position for the ablution room. Information on these and other points is accumulating. Thus the 1924 Report on the Health of the Army noted the opening of a central ablution room at Quetta, where out of 4788 men treated in ten months only two had developed disease. Brevet-Colonel A. H. Safford and Major R. C. Paris give further details in the *Journal of the R.A.M.C.* for November. The room is adjacent to the main infecting area, in a recess just off the direct road back to barracks. Free use is made of it, the authors state, if it is open from 2 P.M. until men are due back to barracks, if it is kept scrupulously clean and bright by two specially selected orderlies, if no names are taken and only numbered tallies given, and if the specialist officer keeps the service always on the highest level. In three years among 16,000 men who used the room only one case of syphilis developed, seven of soft chancre, and 27 of gonorrhœa. Before this room was opened venereal incidence in Quetta was the same as in all India; now it is only one-half. In India the home prophylactic packets began to be issued in May, 1925; the rate for admission to hospital on account of venereal disease fell from 75 in 1924 to 72 in 1925, and to 62 in 1926. Experience of prophylactic measures in the American Expeditionary Force is recorded in a review on p. 1241 of our issue of Dec. 10th.

ARTIFICIAL DEFORMATION OF THE SKULL.

To the Editor of THE LANCET.

SIR,—My attention has been called to an article with the above title in THE LANCET of Nov. 5th (p. 1001) by Mr. Warren R. Dawson, in which the writer draws conclusions as to the origin of the practice of artificial deformation of the skull in Egypt from what he honestly believes to be evidence for such a custom, but which, unfortunately, as will be seen, is only evidence of the way in which facts may be distorted to suit the purposes of persons more interested in making a story than in truth.

The skull upon which Mr. Dawson bases his suggestion was found by Dr. L. Gatineau in a Coptic cemetery of about the fifth century A.D., at Medall, near Faehn, about 100 miles from Cairo. It was brought to Cairo and subsequently was stated to have come from Tell-el-Amarna, nearly 100 miles further south, from the ruins of the town of Akhenaten. Dr. Gorgy Sobhy, on the strength of this statement, and from the *seeming* resemblance of the skull in shape to the heads of Akhenaten, his daughters and other people represented on the monuments and in the statues of the period, examined and measured the skull but made no restoration of it. He, however, gave it as his belief that it belonged to a female member of the family of Akhenaten, and published his account in the *Bulletin de l'Institut Français*, t. xiv., with photographs both of the skull and of a wax model made by Dr. Gatineau, to represent what he imagined would be the appearance of a woman with a skull of this shape. If, however, the skull and model are examined, it will be seen that while the model resembles the stone heads from Tell-el-Amarna, it in no way agrees with the skull upon whose shape it is supposed to be based. The peculiarities of the deformed skull, due to the method of bandaging which h been employed to distort it, are its length, narrowness, a height, whereas the statues are remarkable for their wid and flatness, as are also the actual skulls of both Akhenat and Tut-ankh-Amen.

The skull is undoubtedly an example of artificial def mation by bandaging, and the fact that it was taken from Christian cemetery lends colour to my suggestion that t girl was a visitor to Egypt from the Caucasus, where t practice is, I am told, still in vogue.

In the year 1923, hearing that Dr. Gatineau was selli his effects, I bought the skull and wax model and took th to London. They were purchased for the Museum of t Royal College of Surgeons, where they may be seen.

In the meantime Dr. Gatineau had himself published short note of his excavations at Medall, and in this he gi photographs of some of the skulls found there which he ca "Crânes de martyrs Coptes chrétiens," and includes in Fig of his paper the photograph of the skull already descri and published in 1918 as coming from Tell-el-Amarn As I write I have in front of me the two papers, in each which the same photograph appears, the one in Gatineau's paper, labelled fifth century A.D., and its p venance given as Medall, the other paper, that of Dr. Sob describing the skull as that of a member of the family Akhenaten, whose town lies 100 miles south of Medall a whose date is some eighteen hundred years earlier! making this discovery I communicated with Dr. Sob who thereupon published a correction in the *Journal Egyptian Archæology*, vol. ix., p. 117. This correct Mr. Dawson has unfortunately not seen.[1]

In the whole of my experience in Egypt, where I have s and handled many thousands of crania of all dates, I h never come across another example of deformation bandaging, and it may be taken as certain that the cust did not have its origin in Egypt nor was practised in t country. Mr. Dawson's own quotation from Hippocra who describes the custom as performed in his day in A Minor, is surely evidence in itself that nothing was kn of it in Egypt or Hippocrates could scarcely have failed mention it. I am, Sir, yours faithfully,

DOUGLAS E. DERRY

Anatomy Department, Egyptian University, Cairo,
Nov. 25th, 1927.

TRADE DIARIES AND CALENDARS.

THE Anglo-French Drug Company (238A, Gray's Inn-rd London, W.C. 1) have sent us a copy of their block di for 1928 measuring 6 in. by 4½ in. and showing a page a day. It makes a convenient desk companion and inside of the front cover holds a concise list of the phar ceutical products of the firm.—From Messrs. Oppenhei Son and Company, Ltd. (179, Queen Victoria-street, Lond E.C. 4) we have received a copy of their new edition Ephemeris Pharmacologica, which is in the form of a poc diary and contains an almanac and a visiting-list with bl pages for memoranda and addressses. In addition to b therapeutic notes on drugs and other pharmaceut products useful information is given on poisons and a dotes, drugs and their doses, infectious diseases, heights weights, and so forth. Both these publications are obt able on application.

[1] But see Mr. Dawson's letter in THE LANCET of Nov. 2 p. 1166.—ED. L.

A Review
OF
MEDICAL EDUCATION IN CORK.

Part of a Valedictory Address delivered to past and present Students of University College, Cork, on retirement from the Chair of Surgery.

By C. YELVERTON PEARSON, M.D., M.Ch., F.R.C.S. Eng.,

HON. SURGEON TO H.M. THE KING IN IRELAND; EMERITUS PROFESSOR OF SURGERY IN THE COLLEGE.

PRESIDENT MERRIMAN, COLLEAGUES, AND FRIENDS.—Many of you are aware that the Statutes of the University have very wisely decreed that, apart from other considerations, the term during which any person holds the position of a professor should be determined by an age limitation. Were it not so there would be a natural tendency, on the part of some at least, to cling to office for a longer period than would be desirable in the interests of education. There have been instances in the past where students have had to attend a course of lectures and listen or not, as they pleased, to dissertations on medical subjects which might have been of interest to a previous generation, but were out of date.

I have delivered introductory addresses in this college on three occasions—one, on anatomy, when I entered on the duties of senior demonstrator immediately after graduation; one on taking the chair of materia medica and therapeutics; and one on surgery at the opening of the session following my appointment to that chair. It seems fitting that I should endeavour to review my associations with the past and present medical students of this College now that the time has arrived for me to lay aside the surgical mantle, so that it may be placed on younger shoulders. In doing so I cannot but have regret at ceasing to take an active part in the life of an institution in which I have been occupied as a teacher and other capacities for half a century; but, coupled with that regret, I feel a desire to give expression to feelings which possess me not only in respect of those who have been recently students of my classes, but also in respect of the many who have been within these walls during the period, and with whom my life work has been so largely associated.

In attempting to translate some of my thoughts to words it is difficult to know how to begin, but the following are amongst the many topics which present themselves. The history of the College itself under its various presidents and the numerous changes which have taken place in my time both in structural alterations and in other respects; the influence on the College of changes in the universities with which it has been connected; the history of medical education and the various alterations brought about in the medical curriculum since my student days; professors and colleagues I have known; students I have known. To deal with any one of these subjects in a fitting and adequate manner would occupy more time than could possibly be devoted to it in a short discourse such as I propose to give. My chief desire in the first instance is to pay a passing tribute to some of those much-esteemed teachers, colleagues, and former students who have pased away; to give expression to some of my feelings towards my former students both near and far, and to offer a few words of advice to those who are about to engage in medical studies or to enter upon professional work. In attempting to accomplish this it is impossible to avoid making some references to my own College life which has been closely interwoven with almost everything to which I wish to refer.

A PERSONAL RETROSPECT.

I matriculated in this College in October, 1873. My first year was spent in the arts faculty—where I attended courses under distinguished professors. I cannot say that I took full advantages of my opportunities. As it was my intention to study for medicine I idled a good deal and looked forward with eagerness to the following session, when I was to enter on my medical studies. In those days the first year's course for medical students consisted of French, experimental physics, chemistry, biology, and a combined course of anatomy and physiology. The professor of zoology and botany, Joseph Ray Green, was a learned, distinguished, and eccentric man of whom many amusing stories were current with students. To pass to chemistry, where the professor at that period was Maxwell Simpson, the department at that time was situated on the ground floor beneath the arts lecture-rooms, and, in consequence, fumigated those who occupied them with the odours of sulphuretted hydrogen, chlorine, and bromine, much to the annoyance of the professor of Greek, who was wont freely to denounce all chemists. I cannot find words to express the love and deep veneration which I entertained for that great teacher, Maxwell Simpson, under whom I studied for two years and whose analytical tables are still fresh in my memory. He endeared himself to every student who had the privilege of studying under him. He was particularly liberal in his support to the College clubs, especially to the athletic club, of which he was president and to which he presented a valuable cup. In those days the subjects of anatomy and physiology were combined under one professor and the course of lectures in the first year consisted of an account of the anatomy of the parts, such as the heart or digestive organs, before dealing with a description of their functions. The anatomical lectures were illustrated in a beautiful way by artistic dissections made by the professor himself, Joseph Henry Corbett. He was an eloquent and impressive lecturer, and I was especially fascinated by his treatment of his subjects and obtained a fair knowledge of visceral anatomy before I entered on dissections in my second year. Prof. Corbett was succeeded by an earnest and distinguished teacher, Prof. J. J. Charles, to whom the medical school of our College owed so much of its success during the years that he held the dual and onerous chair of anatomy and physiology, and to whom I personally was indebted for a large amount of my success in life. His name is perpetuated in our annals by the Charles medal which he instituted. Soon after I had passed my second medical examination at the request of several students I formed a class for what was known as "the half" or second medical examination. Amongst the members of that class was the late Dr. Horace Townsend, whose accident, prolonged incapacity, and premature death have been so deeply deplored by all who knew him intimately. Once I had started private teaching I became self-supporting, and during my third medical year I prepared a large number of students for the Queen's University and Edinburgh examinations. In my third year I was appointed junior demonstrator of anatomy, and after graduation I filled the post of senior demonstrator of anatomy, which I held for six years, when I was appointed to the chair of materia medica and therapeutics, vacated through the death of an esteemed teacher, Dr. Matthias O'Keefe.

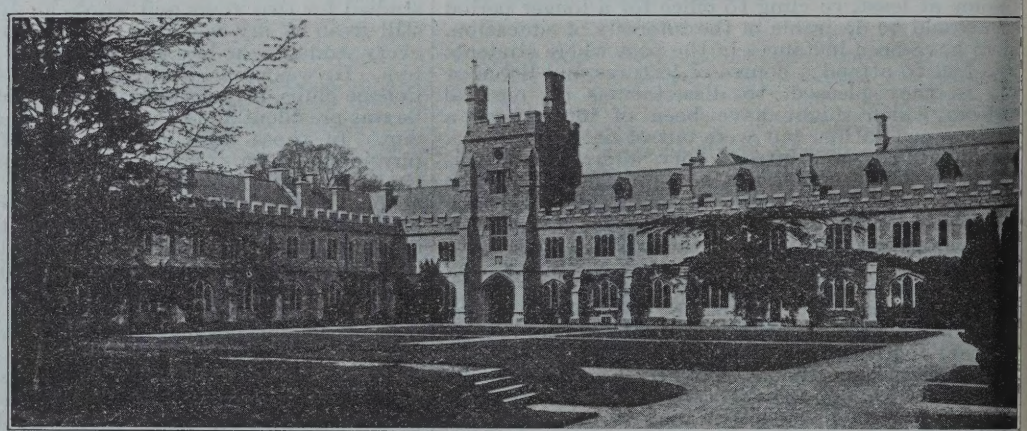
My association with students in the dissecting-room was naturally of an intimate nature, so that I got to know the voices as well as the faces of each member of the class; my memory is still fresh of the students of those early years, amongst whom were Dr. Jeremiah Cotter, a distinguished student and teacher, one of my colleagues on the staff of the North Infirmary up to the time of his untimely death, and Sir Richard Havelock Charles, the Sergeant-Surgeon to the King.

THE COLLEGE BUILDINGS.

In the year 1873, when I entered this College, its first president, Sir Robert Kane, very much an absentee, had resigned, and shortly after Dr. W. K.

Sullivan was appointed. The change from a non-resident to a resident president soon became apparent. At that time the College grounds did not extend much beyond the examination hall and included only a portion of the space now occupied by the gardens connected with the residences of the president and registrar. So that they were bounded, as at present, unfortunately, by the county gaol on the west and on the east by an extensive limestone quarry. The buildings consisted of what constitutes the quadrangle and about one-half of the present medical buildings. At that time the Board of Works was responsible for the maintenance of the buildings, for extensions, and all repairs, but it was not very easy to obtain grants for any new developments. However, owing to the representations and powerful influence of President Sullivan the medical buildings were extended to their present length, the dissecting-room was made double its former size, and the present anatomical and pathological museum was built.

Here I may direct attention to the fact that the eastern ends of the walls of this building were, at President Sullivan's suggestion, left in the rough and unfinished condition which exists at the present day as a monument to the uncompleted work of the British Government. The intention of President Sullivan was to have the building extended so as to complete the quadrangle and provide a spacious library. Such a library is more needed now even than it was then. Further, under the guidance of Dr. Sullivan, our boundaries were extended to their present extent; the limestone quarry was transformed into the beautiful grounds which extend to Fernhurst-avenue; a new entrance with handsome gates was established from the Western-road, but surmounted by a very inartistic building. The bridge which spanned the river from this entrance was a wooden structure provided by the Board of Works, so that obviously it was not intended it should be permanent, and showed signs of decay before many years had elapsed. It was replaced by a concrete one several years ago, but was so constructed that it could not withstand the varying conditions of the river Lee and was swept by a great flood.



View of the Quadrangle of University College, Cork, from the South.

The reason why the College has been left so long without a main entrance is in part the high cost of labour and materials since the Great War and in part the lack of funds. Let us hope that the day may not be far distant when we shall have a suitable entrance and bridge worthy of this beautiful institution. It was owing to the personal influence of President Sullivan that the College benefited so largely by the princely munificence of the late Mr. William Sharman Crawford, who at his own expense erected the plant-houses, built the observatory, and had it fitted with astronomical instruments. He also made a gift of many thousands of valuable books which form the Crawford Library, and he meant to extend his generosity still more extensively if he had not been deterred by the short-sighted policy of the then existing Government.

No important structural changes took place in the College under the reign of President Slattery or that of Sir Rowland Blennerhassett. It is scarcely necessary for me to point out the numerous changes and various additions that have been made during the presidency of Sir Bertram Windle and more recently under President Merriman to any of my present audience, but I wish that many of the older students had an opportunity of inspecting our fine physical and chemical departments, our biological and geological laboratories, and lecture-rooms; the beautiful Honan Chapel, the Honan Hostel, and the College playing-field. They would also find many changes in the physiological and pathological departments in this building necessitated by modern advances in these sciences.

This brings me back to the medical school, which in the past has been the mainstay of this College. The success of our medical graduates has been truly remarkable. On many occasions they have gained the highest places at entrance into naval and military services and more especially the I.M.S. Many have gained great distinction in the Colonial Service and in all phases of medical life. Amongst those teachers to whom the medical school owes so much of its success Dr. Henry MacNaughton Jones deserves more than a passing reference. He had been the chief demonstrator of anatomy under Prof. Corbett, but resigned that position when Prof. Charles was appointed. He was surgeon to the old eye, ear and throat hospital in Nile-street. His efforts there in giving voluntary teaching to any student who wished to attend were indefatigable. He held special evening clinics and taught us the uses of the ophthalmoscope, aurascope, and laryngoscope. He gave most valuable teaching both at the extern and intern departments of the South Infirmary. He was appointed to the chair of midwifery in succession to Dr. Joshua Harvey. If he had been successful later on in getting appointed to the chair of surgery he would probably have remained in Cork and my own career might have been very different.

My immediate predecessor in the surgical chair was Prof. Stephen O'Sullivan who, if not a brilliant lecturer, was a sound and earnest teacher. In more recent years the medical school has lost the invaluable services of my esteemed friend and colleague, Prof. Ashley Cummins. He was one of the most successful and painstaking of clinical teachers; he never spared himself and was a true friend and wise counsellor to all his students.

CHANGES IN MEDICAL EDUCATION.

Briefly reviewing the changes that have occurred in medical education during my time, I should indicate that some of these were due to changes from one university system to another; some of them have been necessitated by the changes due to alterations in the regulations enforced by the General Medical Council. In the days of the Queen's University it was possible for the average medical student to obtain his medical degrees in four years. Let not the student of

the present day imagine that this was an easy matter. The standard of the examinations was so high that about half the students of the Queen's Colleges obtained their diplomas at the Conjoint Examination of the Royal Colleges of Physicians and Surgeons of Edinburgh, and a much smaller number those of the Colleges of Physicians and Surgeons in Ireland. For the standard of knowledge in anatomy and physiology required by the Queen's University was very high. The entire examination for medical degrees had to be passed at one time and not in parts or sections, such as is now permitted. The final examination for the M.D. and M.Ch. included medicine, surgery, obstetrics and gynæcology, pathology, advanced physiology, the whole of human anatomy, and medical jurisprudence, including toxicology. When you consider that candidates had to pass in all these subjects at one examination I think you will have to acknowledge that the lot of the student in this respect is, at the present day, a comparatively easy one. The Queen's University was so constituted that the professors from the constituent colleges formed a board of studies and arranged the courses and examinations. As the examinations were conducted in Dublin by the professors of the three Queen's Colleges all students had an equal chance of obtaining honours and a uniform standard was maintained. Though this arrangement necessitated that all candidates should present themselves in Dublin for examination it had some advantages over the present system.

Owing to the education in the Queen's Colleges being strictly secular they had never received the approval of the Catholic hierarchy; consequently the number of students who entered the arts faculty was very small. Continuous agitation was carried on against the University. The clamouring for an endowed college in Dublin and for another university grew louder and louder, and the fate of the Queen's University was sealed. It was dissolved by Act of Parliament, passed in 1879, and the Royal University was established. This was a very strangely constituted university. It was really a huge examining machine. It granted degrees in almost all faculties outside medicine without requiring any university training. Candidates from schools and from private tuition could obtain the degrees of B.A. and M.A., of LL.B., and of LL.D. without necessarily attending a single collegiate lecture. The Senate consisted of very eminent and excellent men, but one-half of these were Catholics and the other half of other denominations. When a vacancy arose it had to be filled up in accordance with this strange though, I believe, unwritten law. The Catholic University, Stephen's Green, at the outset claimed that, as it received no direct Government endowment or grant, it was entitled to half the examinerships and other posts. After a few years what were called Examining Fellows were created, who received a larger salary than ordinary examiners and held office for a longer period. Thus it will be seen that half the examiners were Catholics and these were connected with University College, Stephen's Green, and it was understood that the other half were to be Protestants of some kind. As the appointments for these had to be divided between the Queen's Colleges, naturally Belfast got the lion's share, while Cork and Galway fared badly. No professor in this College who was a Catholic had a chance of being appointed as an examiner; I owed my own appointment as examiner in medical jurisprudence and hygiene, and later on as a surgical Fellow, to my being a Protestant, and not to any personal merit. Notwithstanding these defects, owing to the high standard of the examinations, the degrees of the Royal University, and especially its medical ones, acquired a very high reputation. As the degrees of M.B., M.Ch., and B.A.O. had all to be obtained at *one* final examination, and owing to the extensive knowledge required of anatomy and physiology, its graduates were more fitted for successfully competing at the examinations for admission to the medical services, and for immediately entering on practice, than the majority of those who graduate under present conditions. But the fact that the degrees of the R.U.I. in art, law, and science could be obtained without any University training naturally had an injurious effect on the Queen's Colleges. The number of students in these faculties became still fewer and both this and the Galway College were threatened with extinction. It was, however, recognised by all who had high ideals of university education that the system of granting degrees by examination alone was not calculated to promote it.

THE IRISH UNIVERSITY BILL.

A Royal Commission was appointed to inquire into the whole system of university education in Ireland and report thereon. The proceedings and reports of that Commission are contained in three or four full-sized Parliamentary Blue-books. In the evidence which I gave before the Commission I advocated the establishment of an endowed college in Dublin, and the reformation of the Royal into a teaching university, to which the four provincial colleges should be affiliated, but that there should be granted such a degree of autonomy as to enable them to have an individual and somewhat independent existence. I am satisfied that if this idea had been adopted it would have been better than what was actually done.

When Mr. Birrell came to Ireland, as Chief Secretary, he probably knew less about this country than most of his predecessors. As the settlement of the university question was then ripe for a solution he set about it, but in a very peculiar manner. It is true he visited Cork and inspected this College and acknowledged that it was worthy of being made an independent university. He did not trouble himself to visit the Belfast and Galway Colleges. When he returned to Dublin he entrenched himself in Dublin Castle, surrounded himself with Parliamentary Blue-books, and interviewed various persons, but was naturally chiefly influenced by the many who were most interested in the aspirations of Dublin. The outcome was the Irish University Bill of 1908, by which two new universities—the National University of Ireland and the Queen's University, Belfast—were established, and on Oct. 31st, 1909, the Royal University was dissolved. Cork had sought for an independent university for Munster, but its claims were set aside; Belfast did not want a separate university, but got one. Reading between the lines it is not difficult to see what occurred. Those who were specially interested in the future of a university college in Dublin feared that the influence on the Senate of Belfast, Cork, and Galway, if combined, might prove embarrassing, so conceived that the best solution of the difficulty was to get rid of Belfast, but letting it have a separate university. Mr. Birrell received a great deal of "kudos," which was largely undeserved, for having solved the Irish university question. His Bill was so vaguely drafted that even the late Chief Baron Pallas, who was a member of the original Senate, declined to interpret many of its clauses without obtaining counsel's opinion. It proved a veritable gold mine to lawyers.

The Royal University had an endowment of £40,000 per annum. This was split, half was given to Northern University, while the National University, which was meant for the rest of Ireland, had to do its best with the other half. Fairly liberal provision was made for the building and endowment of University College, Dublin, and certain provision was made for additional buildings and new professorships in the Cork and Galway colleges, but this was wholly inadequate for their needs and proved even less so as the cost of everything increased during the war. Moreover, a large part of what was given with the right hand was taken away with the left. The British Treasury was no longer responsible for much of the expenditure which it had previously to bear. The Board of Works was no longer required to maintain the buildings, so that the new governing body of this College had to bear all the expenses of structural alterations, and to pay a very large premium on fire insurance.

The more one inspects the provisions of the University Bill the more one realises the injustice that was done to the provincial colleges. The Senate of the N.U.I. is a mixed body, but of its 35 members 17, or practically one-half, are direct representatives of University College, Dublin, while Cork was allotted seven members and Galway five. Again, most of the nominated members are representative of Dublin. Of those elected by Convocation, owing to the preponderance of its graduates on the Register, it follows that Dublin graduates are usually chosen. It is quite evident that by this arrangement the Senate is dominated by University College, Dublin. I do not for a moment suggest that this power has been exercised unfairly; on the contrary, while I was a member of the Senate I found that the Dublin representatives were actuated by a spirit of fairness towards the sister colleges. If, however, any initiative is taken by Galway or Cork in some new direction it has no prospect of succeeding if it does not receive the approval of Dublin.

A UNIVERSITY FOR MUNSTER.

At the time Mr. Birrell was engaged in constructing his University Bill it so happened that I was touring in the United States, inspecting some of its great institutions and visiting its surgical clinics. While being shown over the University of Pennsylvania by one of its professors an amusing incident occurred which I think is worth relating. He suddenly asked me: "Of what university are you a graduate?" I replied: "My answer to that question is one that very few could give: I graduated in a university that no longer exists; I am a graduate of a university that will soon cease to exist, and I then expect to become a graduate of a university that is not yet in existence." Long before that time and ever since I hoped to see the day that I might be registered a graduate of the University of Munster. Whether I shall live for that wish to be fulfilled is in the hands of the Almighty. For I wish to impress upon you all that it is the duty of each one here, of the inhabitants of Cork, and Munster generally, to strive by every legitimate means to obtain an independent university for the South of Ireland so that it may possess that freedom which is so essential for its advancement and development along lines best suited for its prosperity.

When the N.U.I. was established at the very outset the status of its medical degrees was lowered as compared with those of the Royal University, by permitting these degrees to be obtained at separate examinations. This change was made to suit the requirements of University College, Dublin, which regarded itself as starting in rivalry with the medical schools of Trinity College and the Royal College of Surgeons. A further lowering took place by assigning a very subordinate place to physiology and anatomy. This latter defect has to some extent been remedied by the recent enactments of the General Medical Council. I regret to say that the regulations of that body have not given physics or chemistry the position they should hold in the education of the student. There is one other defect in the Cork Medical School which I should much like to see remedied. I consider that the clinical hospitals should be brought into intimate relation and, so far as teaching is concerned, be largely under control of the College. I have made some personal efforts in this direction in the past, but with little success. I was indirectly responsible to a great extent in the arrangement for a rover's ticket. This was only a small step in the right direction. What is also needed is some coöperation between the teaching staffs of the various hospitals, so that the clinical material might be utilised to the greatest advantage. It is a matter of deep regret that owing chiefly to the apathy of many of the younger members of the profession the old Cork Medical and Surgical Society has been allowed to perish. I trust that under altered conditions it may soon be re-established.

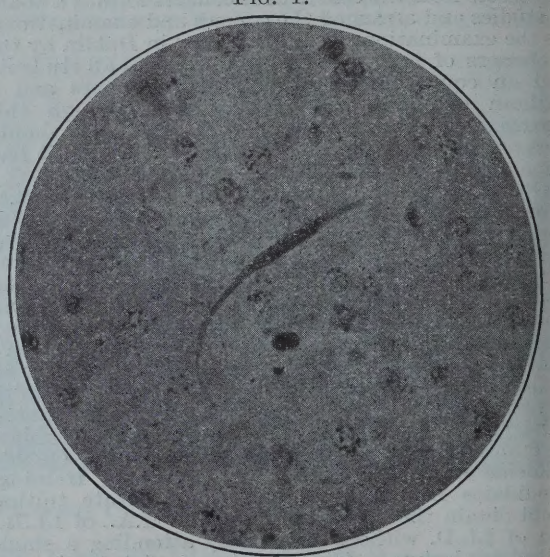
[Prof. Pearson concluded with an eloquent exposition of his views on the relations that should exist between teachers and students.]

A REPORT ON TWO CASES OF TRICHINELLIASIS.

BY T. L. HARDY, M.D. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM.

EARLY in the eighteenth century small Chinese hogs were introduced into Europe for crossing with the native strain in order to improve their fattening powers. Shortly after this there appeared the first cases of a disease which was shown by Zenker in 1860 to be due to an infection by a nematode worm, *Trichinella spiralis*, originally identified by James Paget and Richard Owen and hitherto regarded as a harmless parasite. Zenker was able to demonstrate adult trichinellæ in the intestines and non-encysted larvæ in the muscles during the autopsy on a girl of 19 who had died of a disease thought to be typhoid fever. Salted pork, of which she had previously eaten,

FIG. 1.



Larval embryo in blood film. (×400.)

was found to be heavily infested. Subsequently Leuckhart and Virchow, from material obtained from this case, carried out a series of classical transmission experiments in animals, and the suspicion then aroused that they were dealing with a dangerous disease was confirmed by a succession of outbreaks of trichinelliasis in Germany during the next 20 years, one at Hedersleben in 1865 having a mortality of nearly 30 per cent.

Some authorities attribute the introduction of the disease to the surmulot or Asian brown rat which swam the Volga in vast hordes and overran Europe in 1760. It seems certain, however, that cases of trichinelliasis had occurred, though unrecognised, prior to this date, and although the brown rat has undoubtedly played a part in the dissemination of the disease, the major responsibility must rest on the Chinese pig, which is very susceptible.

In Great Britain trichinelliasis is very rare and apart from an outbreak at Workington in 1871, has never attained serious epidemic proportions. Sporadic outbreaks, however, are occasionally met with, such as those recorded by Harris [1] in 1909, and Rice [2] in 1922. The following notes, descriptive of two cases occurring in the early part of this year, are put on record, since they were seen at an early stage of the illness, ran a mild but very typical course, and lent themselves to thorough investigation.

History of the Outbreak.

The prelude to the story took place on Jan. 16th 1927, when a working-class family of eight persons sat down to their Sunday dinner of roast pork. The

joint, a leg weighing about 9 lb., was roasted in a coal-fire oven for four hours and was apparently well cooked.

On Jan. 21st A. B., one of the party, a woman of 28, felt out of sorts and the normal regularity of her bowels was

FIG. 2.

Area of round-celled infiltration in gastrocnemius. ×200.)

disturbed by two or three loose stools. The following morning she awoke to find her face so swollen that she could not open her eyes. By the next day the swelling of the face had increased and the eyes were bloodshot. Headache was severe, and from time to time she vomited small quantities of bilious material. The evening temperature was 104° F. By the 24th the œdema was considerably less, but on this date severe pain in the calves, thighs, upper arms, and pectoral

FIG. 3.

oreign body giant cells surrounding a dead parasite. (×200.)

muscles was the outstanding feature. Nephritis had been considered as the probable diagnosis, but was negatived by examination of the urine.

On Jan. 26th, ten days after the fateful meal, B. C., the other of A. B., a woman of 48, was attacked in similar fashion, save that in her case the sequence of events—vomiting, œdema, and limb pains—became maximal within hours and she was noticed to have a squint.

On *examination* at this stage both patients presented an appearance of moderate toxæmia, the temperature being 2° in each case; the tongue was lightly furred and there was profuse sweating. The heart sounds were clear and the pulse-rate 120; the lungs were normal. The œdema had largely disappeared from the first patient, but the elder woman had a distinctly "renal" appearance, the swelling being confined to the face. Examination of her nervous system revealed no abnormality other than slight weakness of the left external rectus muscle; there was no diplopia.

FIG. 4.

Encysted parasite in gastrocnemius. (×200.)

The muscular pains had special characteristics and were similarly described by each patient. The slightest movement of the legs or arms produced momentary but excruciating pain, especially in the calves, thighs, upper arms, and pectorals, "as if the flesh was being torn from the bones." Tenderness to palpation was very slight and there was no induration of the muscles. Mastication and swallowing were painless and there was no dyspnœa.

FIG. 5.

Encysted parasite in gastrocnemius. (×400.)

A diagnosis of trichinelliasis seemed probable, and interrogation of the other members of the dinner party revealed the possibility of mild infections in two instances. An old lady of 77 had had pain in the neck and back and some swelling of the face lasting for about a week, whilst puffiness of the face, lasting over 24 hours, had been noticed in a man of 50, who, however, made no other complaint. The two patients were admitted to the Birmingham General Hospital, and confirmation of the diagnosis was obtained by the occurrence of a moderate eosinophilia and the finding

of embryos, both in the circulating blood and later on in various stages of encystment in the muscles.

Blood Examination.

In the early stages there was a moderate leucocytosis with an eosinophilia amounting to 25 per cent. in the one case and 22 per cent. in the other, the increase being obtained, as is usual, at the expense of the neutrophil polymorphs. The eosinophils fell very gradually, normal figures being reached in the one case between the 29th and 41st days of disease, and in the other between the 85th and 91st days (see table). Much higher counts have, of course, been recorded—for example in the paper by T. R. Brown,[3] who was the first to call attention to the value of the sign; an eosinophilia of 68 per cent. is recorded in one of his cases.

CASE 1 (A. B.).

Date in 1927.	Day.	Total.	Neutr.	Lymph.	Monos.	Eosin.	Baso.
Feb. 1	11	17,400	41·8	31·6	1·4	25·2	—

May 17	116	10,240	46·2	44·4	6·4	2·6	0·4
May 26	125	10,080	63·8	29·6	4·4	1·8	0·4

CASE 2 (B. C.).

Feb. 1	6	9,600	53·6	21·2	2·8	22·4	—
Feb. 7	12	—	53·6	23·4	1·0	22·0	—
Feb. 19	24	—	43·6	35·6	5·6	15·2	—
March 3	36	11,200	37·0	47·0	5·8	9·8	0·4
March 14	47	14,200	62·0	24·6	4·4	8·4	0·6
March 25	58	—	45·4	32·4	4·4	16·8	1·0
April 4	68	8,400	43·0	44·2	3·6	8·8	0·4
April 21	85	—	39·8	47·8	3·0	8·8	0·6
May 3	97	9,600	54·6	36·2	5·0	4·2	—
May 17	111	12,200	60·0	32·4	5·0	2·2	0·4
May 26	120	12,400	50·6	37·6	6·8	2·8	0·2

Amongst the many conditions characterised by a marked increase in eosinophils acute polymyositis is important, since it possesses certain features (fever, œdema, and muscle pain), in common with trichinelliasis. According to Piney,[4] in this rare condition the eosinophilia persists only for a day or two, thus constituting a valuable differentiating feature.

Blood smears were also taken from the remaining six persons who had eaten the pork, but with negative results.

In 1905 Staubli had settled the disputed point as to the path of migration of the embryos from the intestinal wall to the striated muscles by finding them in the blood stream of artificially infected guinea-pigs, but it remained for Herrick and Janeway [5] to demonstrate them in the circulation of man. They used Staubli's method, which consisted in laking the blood with ten parts of 3 per cent. acetic acid and examining the centrifuged deposit. The embryos are found in the circulating blood between the eighth and the twenty-fifth day after infection, though according to Gerlach the greatest concentration takes place between the twelfth and twentieth day. In my own cases, and using Staubli's method, embryos were found in the blood stream of the younger patient on the eleventh day (Fig. 1), but not after that date, nor at any time in the elder patient.

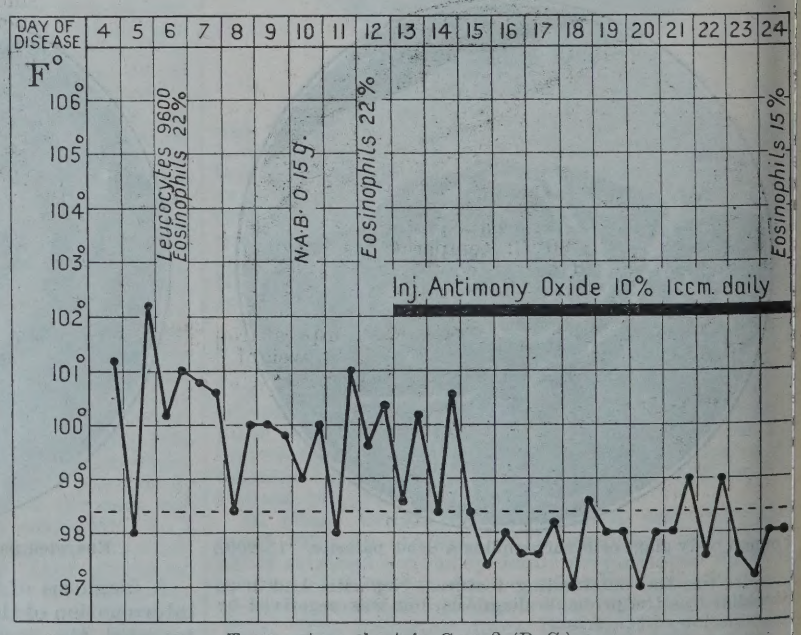
Embryos in the Muscles.

Trichinella larvæ reach the voluntary muscles about a week after infection, their progress being arrested here by the small size of the capillaries, which are further narrowed by muscular contraction.[6] After a preliminary period of migration in the intermuscular connective tissue they penetrate the muscle-fibres, attain their full growth, and enter upon the stage of encystment about one month after infection. Prior to this an interstitial myositis is set up and there is an infiltration of round cells, amongst which are numerous eosinophils surrounding the parasites. Microscopical examination of fragments of voluntary muscle constitutes the most reliable method of diagnosis, the masseters, triceps, and gastrocnemii being the most likely sites. In the cases now described fragments of the outer head of the gastrocnemius, as near the tendinous insertion as possible, were removed under local anæsthesia in the second and seventeenth weeks respectively. Portions of the fresh muscle were teased out in normal saline and examined at once with a hand lens, but with negative results. Fairly thick paraffin sections were cut and stained with hæmatoxylin and eosin. The results are seen in Figs. 2, 3, 4, and 5. Fig. 2 shows the appearance during the second week. Parasites are not seen, but a well-marked infiltration of the muscle-fibres with round cells is present. Figs. 3, 4, and 5 show the embryos in various stages of encystment in the fifth month. Some round cell infiltration is still present, and in Fig. 3 one or two foreign body giant cells are seen; the cyst wall is in process of formation and some detail of the structure of the embryo as it lies curled up within is apparent. The final stage is reached with the deposit of lime salts in the cyst walls—a process which sets in somewhere about six months after infection. Numerous radiograms of the muscles in both patients were taken during the eighth month, but evidence of calcification was not forthcoming.

Clinical Course, Progress, and Treatment.

The progress of both patients was uneventful and similar. The œdema disappeared about the 6th day, and there was complete freedom from pain on movement by the 12th and 13th days respectively. A legacy has developed more recently, however, in the form of gnawing pains, uninfluenced by movement, in the calf and pectoral muscles. Otherwise the general condition of both patients is excellent. The temperature and pulse-rate reached normal on the 15th day in each case (Fig. 6).

FIG. 6.



Temperature chart in Case 2 (B. C.).

No treatment so far introduced has been shown to ave any specific effect in cutting short the infection r destroying the parasites, and reliance has to be laced on the patients' own powers of resistance. arious vermifuges, serum from convalescent patients, rsenic in organic form, and more recently antimony, ave been tried, but without convincing results. In y own cases, after preliminary doses of santonin and vo of N.A.B., antimony in the form of Martindale's ntimony oxide (a 10 per cent. solution in glycerine) as given daily in 1 c.cm. doses intramuscularly over period of a fortnight, beginning on the 13th and 20th ays of disease respectively (Fig. 6). No definite ffect could be attributed to the drug, though ncouraging results have been recorded,[7] and it eems to be worth an extended trial. To be of alue, however, it must be given early in the igratory phase, a condition which presupposes early agnosis, which is rarely possible.

Public Health Aspects.

An account of the public health aspects of these ses has already appeared elsewhere from the medical fficer of health for Smethwick, where the outbreak curred, and the following details are abstracted ainly from his article.[8]

The pork was purchased from a local butcher who ceived it from Birmingham. The Birmingham holesaler bought the pig among 15 others from a large rm which sells about 40 pigs weekly, and is one of e best managed and equipped in the district. The rm was visited by the chief veterinary inspector of rmingham, but no light could be thrown on the use of the outbreak. The farmer does not import y meat from the continent and his pigs are fed on ain, no meat offal being given to them. Four rats hich were obtained from the farm were examined trichinelliasis with negative results.

The cases were notified on the 14th day after ection and all practitioners in the locality were mediately circularised. No further cases have curred, and in the subsequent microscopical examiation of over a thousand carcasses at the Birmingham ughter-houses no trichinellæ have been discovered. is unfortunate, too, that since all the affected pork this case was sold fresh and none pickled, it has en impossible to obtain any trichinous meat. The gin of the outbreak thus remains a mystery.

The prevention of trichinelliasis by meat inspection t best a partial method and is relied upon only in se countries where pork is eaten raw. Elsewhere ance is placed on the destruction of parasites by quate cooking, but this method, too, may prove rustworthy owing to the tolerance of trichinellæ eat. Various observers[9] have placed this tolerance 60°, 70°, and even 80° C., temperatures which are ely if ever reached at the centres of large joints ked according to customary ideas. For example, s Woodhead[10] showed that boiling and roasting rdinarily performed rarely produced a temperature 0° C. at the centre of joints over 6 lb. in weight, similar results were obtained by Robertson[11] in eriments carried out during the war to determine rapidity with which the centre of a piece of meat ld be heated by boiling.

ur comparative immunity from the disease would s seem to depend more on the freedom of our ve pigs from trichinelliasis than upon our methods ooking.

Summary.

wo sporadic cases of trichinelliasis have been ribed, of a type sufficiently definite to admit of ly clinical recognition, but not severe enough to confounded with such conditions as enteric. gnosis was confirmed by finding the embryos in blood stream and in the muscles. The source of outbreak could not be traced, but its occurrence is e attributed to the failure of the ordinary methods ooking when dealing with large joints.

y best thanks are due to Dr. Stanley Barnes for pportunity of continuing the investigation of these s after admission to his wards; to Prof. Haswell Wilson for the microphotographs; and to Sir John Robertson, the late medical officer of health for Birmingham, for his interest and help throughout.

ATRIO-VENTRICULAR RHYTHMS.

BY E. NOBLE CHAMBERLAIN, M.D., M.R.C.P. LOND.,
BEIT MEMORIAL RESEARCH FELLOW; HON. ASSISTANT PHYSICIAN, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

THE impulses initiating the contractions of the heart arise normally in a collection of specialised neuromuscular tissue at the entrance of the superior vena cava into the auricle. This "sino-auricular node" generates rhythmic impulses at an average rate of 72 per minute. Under certain conditions, however, its work may be undertaken by similar neuromuscular tissue scattered throughout the genetic system of the heart, but mainly found in the auriculo-ventricular node and bundle. The rhythms arising from these junctional tissues are therefore commonly called atrio-ventricular rhythms. Two main groups of such rhythms may arise. First, paroxysms of tachycardia of A.V. (atrio-ventricular) nodal origin and single premature beats from the same source called nodal extrasystoles. Secondly, a slow rhythm of the heart due to the gradual transference of the pacemaker from the S.A. (sino-auricular) node to the A.V. node. The latter is properly called atrio-ventricular rhythm, though the term "nodal rhythm" is frequently applied to it. Closely allied to A.V. rhythm is the condition of "ventricular escape,"[1] in which, during the course of an S.A. rhythm, occasional beats of the ventricle arise from impulses formed in the junctional tissues. Ventricular escape thus bears much the same relationship to A.V. rhythm as do extrasystoles to paroxysmal tachycardia, A.V. rhythms representing a more permanent condition of ventricular escape, and paroxysmal tachycardia representing a continuous series of extrasystoles.

The two groups of ectopic rhythms referred to here were classified by Lewis[2] as heterogenetic and homogenetic respectively, and differ in several important characteristics. The heterogenetic rhythms—e.g., paroxysmal tachycardia—are rapid in rate, abrupt in onset and cessation, and uninfluenced by factors such as exercise or change of posture. The homogenetic rhythms (A.V. rhythm) are slow in rate and gradual in onset and cessation, and are considerably influenced by exercise, vagal stimulation, &c. This paper is concerned with the latter group; the inclusion of ventricular escape under the heading of atrio-ventricular rhythm seems justified by their close relationship.

Causes of A.V. Rhythm.

It is sometimes stated that the heterogenetic rhythms are pathological in origin, whilst the homogenetic are physiological. Whereas the former statement is probably true, the latter is only partially correct, for, although A.V. rhythm may arise in an apparently normal heart without any obvious cause, it is not uncommonly a feature of some cardiac disability due to disease. Experimentally the rhythm has been produced by Lewis,[3] Meek, and Eyster,[4] and others, on the one hand, by methods which depress the S.A. node, such as cooling with iced water or

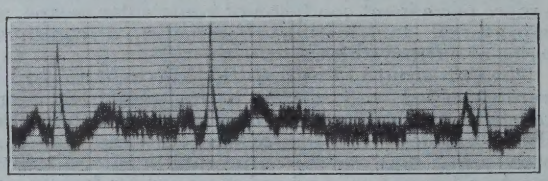
making incisions round the node, and, on the other hand, by enhancing the function of the A.V. node by warming or electrical stimulation. All these methods act by increasing the rate of impulse formation in the A.V. node relative to their formation in the S.A. node. The rhythm has also been produced by simultaneous stimulation of the right vagus and left sympathetic. Wilson[5] has shown that it can be produced in a considerable percentage of normal individuals after subcutaneous administration of atropine, and that it lasts 15–20 minutes before reverting to a sinus rhythm. This writer[6] has also shown that deep respiration may initiate an A.V. rhythm. Amongst drugs which are likely to cause it digitalis holds an important place, though the condition has also occurred under ether anæsthesia. The pathological states in which A.V. rhythm has been noted are mainly infections such as diphtheria, scarlet fever, typhoid, infective endocarditis, and rheumatic fever. The experimental methods of induction help to explain its occurrence in these infections, for the latter so damage the sino-auricular node that its function is temporarily in abeyance, and the A.V. node then governs the rhythm of the heart. It seems less probable that the toxins of the disease may stimulate the A.V. node and increase its period. In either case, when the rhythmicity of the A.V. node exceeds that of the S.A. node in rate, atrio-ventricular rhythm results.

Clinical Features of A.V. Rhythm.

The number of recorded cases of A.V. rhythm and ventricular escape does not justify any sweeping conclusions on the symptomatology of these conditions. It would appear that A.V. rhythm may occur without any symptoms at all, as in the case recorded here, and may be discovered incidentally in the examination for some other condition.

Gallavardin and Gravier[7] and others have noticed in cases of persistent A.V. rhythm a tendency to

FIG. 1.

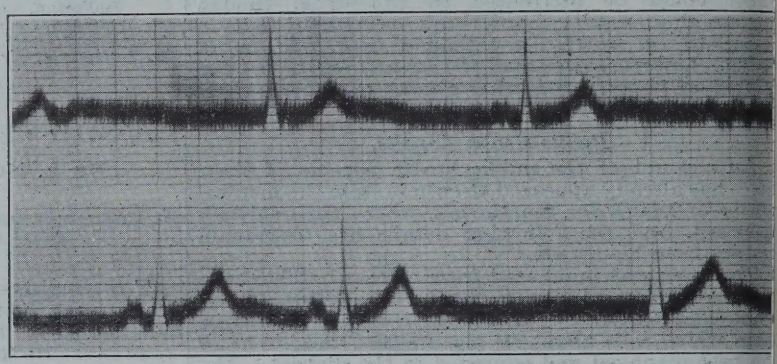


(Lead II.) Shows an isolated cardiac cycle with P.R. interval less than normal—i.e., A.V. rhythm, Type I. The time is marked in 1/5th secs. in all the figures.

vertiginous attacks suggestive of those occurring in heart-block. These may possibly be accounted for by ventricular standstill, which might occur from any excessive action of the vagus. Wilson observed palpitations in two of his cases of A.V. rhythm produced by atropine, and found that they were associated with simultaneous contraction of the auricles and ventricles.

The *physical signs* of A.V. rhythm are variable, but in most cases bradycardia is one important feature. The rate varies from 45–55. Sometimes the pulse is perfectly regular, though more often it shows periods of irregularity which resemble the intermissions of partial heart-block. Examination of the heart generally reveals nothing of importance unless some other coincident lesion is present. Whilst these signs may suggest the possibility of A.V. rhythm, th diagnosis cannot be established without graphi methods of investigation. Most cases of A.V. rhythr are temporary, and if induced by drugs such a atropine or digitalis revert to the normal S.A. rhythr as the effect of the drug passes off. The cases occurrin spontaneously or after infections seem liable to recu from time to time. The literature of A.V. rhythr records a few examples lasting over a long perio but a true permanent A.V. rhythm is very rare.

FIG. 1 (A).



Shows ventricular escape. Note absence of P wave in first cycle, lead I., and ir third cycle, lead II.

The following case illustrates certain of the poin mentioned in this paper, and the electrocardiogran are taken from this patient.

Dock labourer aged 46. Admitted to Royal Southe Hospital Jan. 23rd, 1927, with dysarthria from right faci palsy of lower neuron type.

Past History.—No illnesses of note. No rheumatic infe tion. Denies venereal disease. Wassermann negativ Wife had no miscarriages. Alcohol and tobacco moderat

Present Condition (Jan. 26th, 1927).—No cardiac symptor except slight breathlessness. Apex beat in fifth intercost space, 4 inches to the left of middle line. Heart soun normal. No bruits. Rhythm irregular, but not grossly s Apparent intermissions of the pulse. Pulse-rate varied fro 40–70 per minute on different days, commonly about per minute. Electrocardiograms taken Jan. 26th and 29 show the characters of A.V. rhythm mixed with tho of S.A. rhythm—i.e., "ventricular escape" occurring frequent intervals. (Figs. 1 and 1 (A).)

Effect of Atropine.—Feb. 3rd, 1927. Patient given 1/30 g atropine sulp. hypodermically. Ventricular rate rose 124 at the end of half an hour, and after 40 minutes fell 69. During the administration of atropine the rhyth became quite regular, and the electrocardiogram shows continuous A.V. rhythm of Type II.

Effect of Digitalis.—Later the patient was kept on da doses of 1 drachm tinct. digitalis for 10 days. The effe was to reduce the rate of the ventricle and to produce continuous A.V. rhythm of Type III.

Later Observations.—The patient was re-examined fi months after the above observations were made. T pulse-rate was still slow (average 52 per minute). A. rhythm was still recognisable in the electrocardiogran The persistence of the condition suggests the possibility fibrotic changes round the S.A. node.

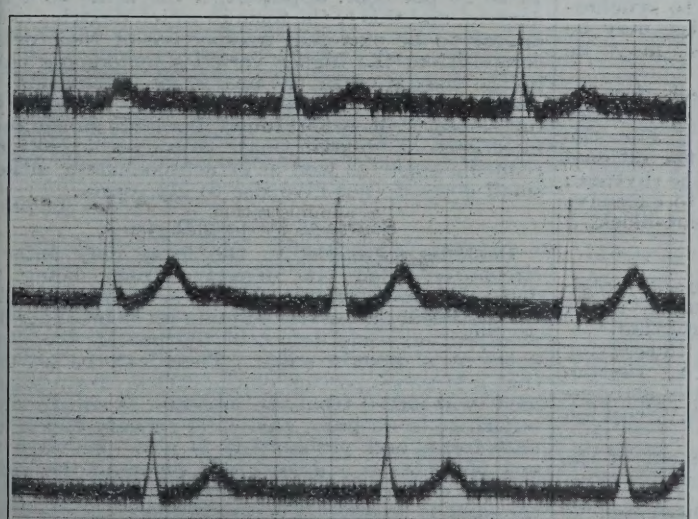
Electrocardiographic Considerations.

The diagnosis of A.V. rhythm is only to be ma with certainty by means of electrocardiograms, a these may offer some difficulty in interpretation, not uncommonly in the same record there may frequent changes from an S.A. to an A.V. rhyth and vice versa—a condition usually described ventricular escape. An example is seen in Fig. 1 (A At other times it is possible that the two pacemake may be simultaneously engaged in producing stimu those from the S.A. node governing the auricle whilst those from the A.V. node govern the ventricle Vaucher and Meyer,[8] recording a case of A.V. rhythm regard their electrocardiograms and those of oth authors as representing such a state of affairs, a

eny the possibility of an A.V. rhythm of a permanent rpe in which all chambers of the heart are governed om the A.V. node. To them the variations in the rm and position of the P wave are due to "interrence phenomena." This means that electrical aves arising from the A.V. node will tend to neutralise rtially or completely those arising in the S.A. node, ving to their spread in opposite directions. Whilst ch interference phenomena undoubtedly occur, it ems probable that in many cases of A.V. rhythm, hether permanent or temporary, the whole heart—th auricles and ventricles—is controlled by the V. node, the stimuli passing from it nultaneously to the auricles and ventricles, d it is only in the transition stages tween S.A. and A.V. rhythm that terference phenomena are met with. In ese cases, when the only pacemaker at rk is the A.V. node, Gallavardin and avier suppose that the variations in the rm and position of the P wave are pendent upon the portion of the auricle on which the impulses from the A.V. node pinge first. Thus a positive P wave dicates that the contraction of the ricles commences near the S.A. node, ilst a negative P suggests that the mulus reaches the part of the auricle ar the A.V. node first. It must be assumed this case, as Gallavardin and Gravier point t, that the stimuli from the A.V. node need t fall first upon the lower part of the auricle—i.e., nearest part to the A.V. node—but may reach upper part first, owing to the distribution of conting tissue in the auricle. The position of the P ve in these cases will depend upon the relative le of arrival in the auricles and ventricles of the mulus from the A.V. node. According to the sition of the P wave three types of A.V. rhythm y thus be distinguished.

Type I.—In which the P.R. interval is present, but rtened. The impulse in this case probably arises the upper portion of the A.V. node. The P wave

FIG. 2.

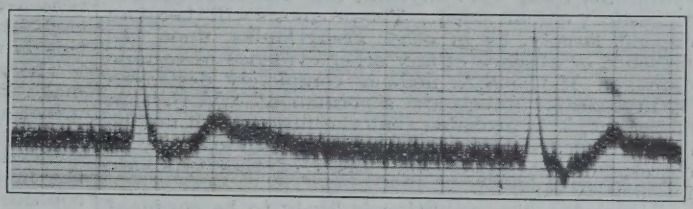


Shows A.V. rhythm, Type II. Note absence of definite P waves in all leads. Small notch on S waves may represent the submerged P wave.

be upright or inverted, as mentioned above, rding to whether the impulse arrives at the upper wer part of the auricle first. An example of this , occurring as an isolated event—ventricular pe—is to be seen in lead II., Fig. 1, where the ular complex shows a shortened P.R. interval a P wave with a sharper summit than normal.

ype II.—In which the impulse arises in the lle of the junctional tissues and spreads simultaneously to the auricles and ventricles. The P wave is thus submerged in the Q.R.S. complex, sometimes being represented by a notch on the R or S waves. The absence of the P wave does not indicate cessation of auricular contraction, as the polygraph shows that in many cases the auricles are contracting simultaneously with the ventricles. Fig. 2 is an example of this type. No definite P wave is present, because it is submerged in the Q.R.S. complex, though it is possible that the slight notch on the S waves may represent P. This example of A.V. rhythm was produced in the patient described by the administration of atropine. The electrocardiogram was taken 40 minutes after the injection of the atropine.

FIG. 3.



(Lead II.) A.V. rhythm, Type III. Note that P waves follow R waves and are inverted.

Type III. is characterised by an R.P. interval of varying length—i.e., the P wave occurs after the R wave because the stimulus from the A.V. node reaches the ventricle before it reaches the auricle. This occurs if the stimulus arises in the lowest position of the junctional tissues or, per contra, in the middle of these tissues, but is associated with defective conductivity of the A.V. bundle. Fig. 3 shows in lead II. A.V. rhythm of this nature. The P wave follows the Q.R.S. complex by an appreciable interval and is inverted. Probably the R.P. interval is induced by depression of conductivity of the A.V. bundle by digitalis, which delays the stimulus in its passage to the auricle. As a general rule it will be noted that the P wave is positive when preceding and negative when following the R wave. A study of the P.R. interval has shown that it varies considerably in length from time to time, suggesting that the position in the junctional tissues from which the A.V. rhythm arises is constantly varying. Possibly this may account for the arrhythmia which is commonly present in A.V. rhythm. Another explanation of this, however, is that the rate of stimulus production undergoes variation. The former explanation seems to be negatived by the observations made by P. D. White that, although the P.R. interval may vary in the same patient from 0·123 to 0·235 on different days, yet the variation from beat to beat is negligible.

Extrinsic Factors Affecting A.V. Rhythm.

P. D. White,[9] studying a case of prolonged A.V. rhythm following auricular flutter, observed the following facts:—

1. Exercise increases the rate of the heart. In the case recorded in this paper the rate rose from 48 to 56 after moderate exercise.

2. Quiet respiration has little effect. Deep respiration produces acceleration with inspiration, and slowing with expiration. This fact was also confirmed in the present case.

3. The effect of atropine was to increase the heart-rate in White's case, but not to restore S.A. rhythm. In the case mentioned here, a partial A.V. rhythm (ventricular escape) was converted into a continuous A.V. rhythm for 15–20 minutes by the administration of atropine.

4. A.V. rhythm is markedly affected by vagal influences, stimulation leading to a decrease in the heart-rate which

may be extreme. On one occasion it has led to a pause of 4 seconds.

5. In White's case digitalis had no effect on the rate of the rhythm, but bigeminy was produced.

In the present case the rate after digitalis was slightly lower than before its administration—45 per minute instead of an average of 52. Further, the rhythm became continuously nodal, and the P wave became more and more delayed in its appearance, eventually following the R wave.

Prognosis, Diagnosis, and Treatment.

From the cases recorded in the literature it would seem that very few patients have any untoward symptoms from A.V. rhythm, and the heart is not necessarily embarrassed. The prognosis will therefore depend largely, as in other arrhythmias, upon the presence or absence of any other evidence of cardiac damage. If the S.A. node is completely destroyed by myocardial fibrosis and a permanent A.V. rhythm is present, it is probable that the fibrosis will not be confined to the S.A. node and the outlook will be correspondingly grave, but cases of this type are fortunately rare.

Diagnosis.—The condition is likely to be confused with other arrhythmias of which bradycardia is a feature, and the importance of its recognition depends upon the different prognosis which attaches to these other irregularities.

1. Heart-block is the most important of these. In complete heart-block the rate of the heart is usually about 30 per minute, and regular, whilst in A.V. rhythm it is commonly 45–55 and irregular. Difficulties may arise, however, if the heart-block is associated with premature beats. Partial heart-block may so closely resemble A.V. rhythm that a diagnosis can only be established by means of electrocardiograms or polygrams. The diagnosis between the two conditions is obviously of considerable importance, as partial heart-block is almost invariably a more serious lesion than A.V. rhythm.

2. Auricular fibrillation is sometimes associated with bradycardia, but as a rule the rhythm is more completely irregular than A.V. rhythm. Absence of jugular pulsation in fibrillation or the presence of unduly large waves in A.V. rhythm, due to synchronous contraction of auricles and ventricles, may be helpful points, but electrocardiograms may be necessary.

Treatment.—Generally A.V. rhythm calls for no special treatment, unless it is a part of some other cardiac disability requiring attention. For the vertiginous attacks atropine would seem the rational drug to employ, as it increases the rate of the rhythm; it is probable that these attacks are due to excessive slowing of the heart, similar to that of heart-block.

Summary.

1. The close relationship of A.V. rhythm and ventricular escape seem to justify their inclusion under the common heading of atrio-ventricular rhythm.

2. A case of A.V. rhythm is described, illustrating its occurrence occasionally during S.A. rhythm (ventricular escape), and the effect upon it of atropine and digitalis in producing a continuous A.V. rhythm of Types II. and III. respectively.

3. A suggestion is made for the treatment of the attacks of vertigo which are liable to occur.

I am indebted to Dr. C. Hamilton Owen and to Dr. N. B. Capon for permission to investigate the case described here. My thanks are also due to Dr. John Hay for valuable advice, and to Sir Thomas Lewis, who kindly gave his opinion on some of the electrocardiograms.

DEXTRINURIA: ITS CLINICAL SIGNIFICANCE.

BY P. J. CAMMIDGE, M.D. LOND.

THE diagnostic significance of an excess of carbo hydrate in the urine may be said to date from th discovery by Trommer of a simple and striking tes for reducing sugars. This was described in 1841, afte Trommer's death, by Mitscherlich. The simplicity c the test and its modifications, and the undoubte clinical value of its results, have focused attentio almost entirely upon the reducing sugars, so that th presence of abnormal amounts of other forms c carbohydrate is largely ignored; I hope to prove tha this is unfortunate.

The physical characteristics of starch and glycoge make it unlikely that either can be excreted in th urine, although Leube [1] discovered what he believe to be glycogen in severe diabetes, and Hirsch [2] ha claimed that starch granules may be passed afte the ingestion of raw starch. Voigt was unable t confirm Hirsch's experiments, and Simon has show that Leube's findings were caused by glycogeni degeneration of the kidneys, so that the occasiona occurrence of these substances in the urine apparently to be attributed to local causes. Th higher intermediate products of starch or glycoge hydrolysis and digestion, known collectively a dextrins, are colloidal, and so are not likely to b excreted by the kidneys unchanged, but the lowe soluble forms can probably pass readily into th urine without material alteration. Experiments upo animals have shown that dextrins gaining entrance t the systemic circulation are largely excreted in th urine. P. Mayer [3] recovered 34 to 50 per cent. of th dose when 10 g. of erythrodextrin were injected sul cutaneously into rabbits, while Mendel and Mitchell working with rabbits and cats, recovered fro 0·22 to 0·88 g. after the injection of 2 to 3·5 g. of th mixed dextrins prepared by the action of saliva o starch. Fritz Voit,[5] after the injection of amyl dextrin into human beings, found that fro 10 to 28 per cent. appeared in the urine as achro dextrin, and this is the form in which dextrins usuall appear to be excreted, irrespective of their origin composition, the higher varieties undergoing chang in the tissues or in the process of elimination. I some circumstances the change may apparently g further, for F. M. Allen[6] found that large subcutaneou injections of dextrin may cause an excretion c reducing sugar as well as of achroodextrin, althoug small doses do not give rise to glycosuria.

Source of Urinary Dextrins.

Dextrins appearing in the urine may enter th circulation from the digestive tract, being the derived from starch, or may be produced withi the organism during the building up or breaking dow of glycogen, some defect in the process stopping short at a dextrin stage. There can be no doul that a large proportion of the carbohydrate taken a food is absorbed from the intestine as simple sugar but there is no proof that it is entirely taken up i that form, and probably it is not. In vitro it not possible to convert into sugar all the dextri formed during the process of starch digestion, an the same is no doubt the case in the alimentary trac Otto [7] and v. Mering [8] have both demonstrated tha carbohydrates resembling dextrins are present in th blood of the portal vein during active carbohydra absorption, so it seems that the unchanged dextrin are absorbed. The tolerance of most animals fo dextrins given by the mouth is high, although th actual limit and the effect of an overdose appear t vary with the species. Rabbits, for example, hav been shown by Jones [9] to be very tolerant, wheth the dextrin is given orally or subcutaneousl Schwarz [10] found that rats, on the other han invariably pass hydrolysable carbohydrate in the urine when fed on a diet of cooked starch, probabl

owing to the contained dextrins, as F. M. Allen [6] has proved that the same effect is not produced by a diet of uncooked grain. In human beings Folin and Berglund [11] showed that dextrinuria can be produced by large dextrin meals and that the excretion of polysaccharides continued for three or four days after the special diet had been discontinued. Working with rabbits, Mr. Howard and I [12] found that dextrins given by the mouth are largely absorbed as such into the portal circulation, but that on reaching the liver they are almost completely retained, only traces passing into the systemic circulation. If, however, the functions of the liver have been interfered with by the previous subcutaneous injection of a small dose of an hepatic poison, such as hydrazine phosphate, hydrolysable carbohydrate appears in the peripheral circulation in abnormal amounts and dextrins are excreted in the urine. It would therefore seem that the tolerance of an animal for dextrins given by the mouth is related to the functional activity of its liver and that pathological alimentary dextrinuria is to be regarded as an expression of hepatic insufficiency, but not necessarily of gross anatomical changes, since dextrinuria can be produced in apparently healthy people by overworking the liver. Willheim [13] and Langer [14] found that dextrinuria may follow the administration of dextrose or lævulose to healthy individuals, and later Pekelharing and Van Hoogenhuyze [15] showed that, if 175 g. of cane sugar were taken daily for four days, the amount of dextrin excreted in the urine increased from 5·4 g. on the first day to 14·6 g. on the fourth, and that on the last day traces of reducing sugar also made their appearance. In the course of our observations we have found that when a small dose of glucose was taken and a second similar dose was administered at the time of the anticipated maximum effect of the first on the blood-sugar, a much longer and more pronounced rise occurred in the hydrolysable carbohydrate than in the reducing sugar of the blood; this suggested that part of the second dose escaped into the general circulation in an imperfectly metabolised form intermediate between dextrose and glycogen, owing to the failure of the liver to carry out its glycogenetic functions completely. Experiments reported by Franke and Wagner [16] tend to support the view that the liver is the organ responsible for, experimenting with dogs, they found that if the organism were flooded with large doses of glucose by intravenous, intraperitoneal, or rectal injection, so as to avoid the normal absorption path through the portal circulation, hydrolysable carbohydrate appeared in the blood within a very short time, and that as it increased there was a diminution in the fermentable reducing sugar.

Disturbance of the Liver, Pancreas, and Pituitary as Causes of Endogenous Dextrinuria.

An abnormal excretion of hydrolysable carbohydrate in the urine, independently of feeding, can be produced experimentally in animals in several ways. We have seen that the subcutaneous injection of a small dose of hydrazine phosphate causes alimentary dextrinuria in rabbits, in spite of their high natural tolerance for dextrins. Further experiments [12] have shown that, if the rabbits are kept without food and a second larger dose is injected 24 hours later, the percentage of reducing sugar in the blood falls and the proportion of hydrolysable carbohydrate increases, while hydrolysable carbohydrates appear in the urine, as the functions of the liver are progressively interfered with by the poison, until, shortly before death occurs, some two-thirds of the total carbohydrate of the blood may consist of non-reducing hydrolysable material and only one-third of reducing sugar. In these circumstances the hydrolysable carbohydrate in the blood and urine can only be of endogenous origin and is probably derived from the stored glycogen of the liver which the poisoned cells are unable to break down completely to the normal end-product of sugar. Disturbances in the functions of the pancreas are probably a much more common cause of endogenous dextrinuria than disease of the liver, since with the latter it apparently occurs only at an advanced stage, whereas with the former it is one of the earliest effects. Experiments I carried out with Dr. H. C. G. Semon in 1908 [17] demonstrated that when subacute pancreatitis was produced in dogs by injecting a small quantity of turpentine into the pancreatic duct, a large excess of non-reducing hydrolysable carbohydrate appeared in the urine within 24 hours, although a similar injection into the common bile-duct had no such effect. We also found that there was an unmistakable increase in the excretion of hydrolysable carbohydrate when chronic pancreatitis was induced by passing a silk thread from the duodenum along the duct of Wirsung, and that if the pancreas was subsequently excised the excess of hydrolysable carbohydrate disappeared from the urine and was replaced by fermentable reducing sugar. Later observations upon animals, conducted with the help of Mr. Cairns Forsyth and Mr. Howard,[18] have confirmed these results and shown that an experimental diminution of the internal secretion of the pancreas, produced by removing a portion of the gland, invariably gives rise to an increase in the proportion of hydrolysable carbohydrate in the fasting blood and an excretion of dextrin in the urine, and, further, that as the control of the pancreas over carbohydrate metabolism is rendered less and less efficient by excising larger portions, the excess of hydrolysable carbohydrate in the blood is gradually replaced by hyperglycæmia, and the dextrinuria by glycosuria, of increasing intensity. In a one-third depancreatised dog, for example, we found a fasting blood-sugar of 100 mg. per cent. and a hydrolysable carbohydrate of 300 mg. per cent. In a two-thirds depancreatised animal the fasting blood-sugar stood at 130 mg. per cent. and the hydrolysable carbohydrate at 170 mg. per cent., while in a practically depancreatised dog there were 190 mg. per cent. of reducing sugar and only 10 mg. per cent. of hydrolysable carbohydrate. The urine of the first animal contained a pronounced excess of dextrin, the second less, and in the urine of the totally depancreatised dog none could be found. As these results were obtained after an eight or ten hours' fast, alimentary dextrinuria can be excluded and an endogenous origin for the excess of hydrolysable carbohydrate in the blood and urine seems to be the only explanation. The influence of feeding upon the carbohydrate content of the blood of partially depancreatised animals suggests that the excess of hydrolysable material present in the fasting blood is derived from the stored glycogen of the tissues, for the percentage is found to fall in proportion as the percentage of reducing sugar increases, and rises again as the sugar diminishes (Fig. 2). This indicates that when a fresh supply of sugar is available to meet the needs of the body, and there is consequently a diminished call upon its reserves, a corresponding reduction occurs in the proportion of imperfectly metabolised sugar entering the blood. A third possible cause of endogenous dextrinuria is defective glycogenolysis arising from the abnormal activity of influences having an effect upon carbohydrate metabolism opposite to that exerted by the internal secretion of the pancreas, so that, although the latter is actually formed to a normal extent, there is a relative deficiency. Experiments rendered possible by the discovery of insulin have proved that pituitrin combines chemically with insulin at the average reaction of the blood and that adrenalin is physiologically antagonistic to insulin.[19] An excess of either in the blood may, therefore, be expected to have the same effect as a corresponding deficiency of the internal secretion of the pancreas. The results of subcutaneous injections of these substances tend to support this view, since an increase occurs in the hydrolysable carbohydrate of the blood, varying in degree with the strength of the dose employed. Demonstrable dextrinuria is difficult to produce experimentally in this way, but it seems likely that hyperactivity of the pituitary, and probably also of

the suprarenals, must be considered as possible causes of pathological dextrinuria, judging from the pronounced excess of dextrins found in the urine, and of hydrolysable carbohydrate present in the blood of several cases of acromegaly which I have examined. As our experiments have also shown [12] that electrical stimulation of the vagus is associated with a similar increase in the hydrolysable carbohydrate of the blood, nervous influences may possibly play a part in the production of dextrinuria in some circumstances.

The occurrence of dextrin-like substances in the urine was first demonstrated, in 1894, by Baisch,[20] who showed that the "animal gum" described by Landwehr in 1882 [21] was mainly of this nature. Baisch, and most observers who have since investigated the subject, separated the dextrin as an insoluble benzoyl ester. Prepared in this way, it is found to be an amorphous, tasteless, odourless substance which dissolves completely in water to give a clear solution. The aqueous solution is feebly dextro-rotatory, is not fermented by yeast, and does not give a brown coloration with iodine. It does not reduce alkaline solutions of copper or bismuth, but yields a reducing unfermentable substance giving the orcin and phloroglucin reactions of a pentose (xylose) on being boiled with dilute hydrochloric or sulphuric acid for a short time, and fermentable reducing sugars on more complete hydrolysis. Urinary dextrin is insoluble in alcohol and ether, is precipitated from aqueous solution by soluble salts of mercury or lead, and is also precipitated from strongly alkaline solutions by copper salts. On being boiled with strong hydrochloric acid it forms furfuraldehyde and gives a furfurol reaction with α-naphthol. Heated with nitric acid it yields oxalic acid. Purified urinary dextrin is free from nitrogen and, according to our analysis,[22] contains carbon 43·8 per cent., hydrogen 6·2 per cent. and oxygen 50 per cent., with a probable formula $(C_6H_{10}O_5)_n \cdot C_5H_9O_5$.

Clinical Tests for Dextrin.

The separation of dextrin from urine by the benzoyling process is far too long and elaborate for clinical purposes, and other simpler, though less exact, methods have to be relied upon for detecting its presence. Landwehr employed precipitation with copper sulphate, after the urine had been made strongly alkaline with caustic soda, but the results are very uncertain unless a high percentage of dextrin is present. In 1904 I described a more delicate test [23] in which the sugar, formed on boiling a urine containing dextrin for a short time with dilute hydrochloric acid, is separated as a crystalline osazone, after the excess of acid has been neutralised with lead carbonate and any glycuronic acid which may be present has been removed with tri-basic lead acetate. This test was originally devised merely as a means for assisting in the clinical differentiation of chronic pancreatitis from malignant disease of the head of the pancreas, a purpose which it served reasonably well, and it was not until some time later that its exact significance was realised and proof of its underlying cause was obtained.[24] As a clinical test for dextrinuria it is still the simplest available, but care is required in its performance and suitable controls are needed to exclude other substances forming crystalline osazones. Since traces of dextrin may occur in normal urines and cause difficulties, and some cases of pathological dextrinuria pass a small excess of sugar in their urine, it is safer to adopt a quantitative process and estimate the reducing material formed on heating the urine with hydrochloric acid under standard conditions. The method now employed in my laboratory is carried out as follows :—

Twenty c.cm. of the filtered urine are placed in a small flask, and 2 c.cm. of hydrochloric acid (sp. gr. 1·16) are added. The neck of the flask is closed with a small funnel and the contents are gently boiled for ten minutes. The excess of hydrochloric acid is then neutralised by adding 5 c.cm. of a saturated solution of sodium carbonate, and the flask is cooled under running water. After making the contents faintly acid with acetic acid and shaking until frothing ceases, they are poured into a 50 c.cm. graduated flask and the transference completed with two or three small washings of water. The contents of the graduate are now well shaken with 5 g. of tri-basic lead acetate, made up to 50 c.cm. with water, allowed to stand for ten minutes and filtered, repeating if necessary until a clear filtrate (A) is obtained. In another graduated flask 20 c.cm. of the original urine are shaken with 5 g. of tri-basic lead acetate made up to 50 c.cm. with water, and filtered, yielding a second clear filtrate (B). Into each of two small flasks is now introduced 10 c.cm. of a specially prepared copper solution * and to one is added 5 c.cm. of the filtrate "A" and to the other 5 c.cm. of the filtrate "B." The necks of the flasks are closed with small funnels and the flasks are heated in a boiling saturated solution of sodium chloride for exactly five minutes. The flasks are then cooled in running water and 3 c.cm. of sulphuric acid (30 per cent.) are added to each from a pipette, after which the contents are immediately titrated with freshly made N/100 sodium thiosulphate solution, using three drops of 1 per cent. starch solution as an indicator. The figure obtained by titrating a control, consisting of 10 c.cm. of the special copper solution and 3 c.cm. of sulphuric acid (30 per cent.) with the same dilution of thiosulphate and starch as the indicator, is subtracted from each of the findings. The difference between the results thus obtained, multiplied by 5000 and divided by 6, gives, approximately, the dextrin value of the urine in milligrammes per cent.

This method does not give reliable results in the presence of lævulose, lactose, or maltose, and should not be used when there is more than 0·1 per cent. of dextrose. It is then necessary to employ the modification of Jolles's process for estimating pentose which I described under the name of the "iodine coefficient of the urine" in 1913.[6] In order to obtain figures comparable with those given by the method just described, and to express the result in milligrammes of dextrin per cent., it is necessary to multiply the finding by 50. By either method an excretion of dextrin exceeding 150 mg. for the 24 hours may be considered as abnormal.

Significance of Non-reducing Hydrolysable Carbohydrate in the Urine.

Although it is not strictly accurate to regard all non-reducing hydrolysable carbohydrate materials occurring in the urine and blood as dextrins it is convenient to do so in practice, for, whatever its exact chemical composition may be, the presence of an excess of such material has the same clinical significance and indicates an early disturbance of carbohydrate metabolism. The nature of the disturbance can only be determined, however, by carrying out further tests, since dextrinuria, like glycosuria, is not characteristic of any particular defect. Alimentary dextrinuria, as we have seen, is indicative of an anabolic disorder and is associated with faults in the functions of the liver, while endogenous dextrinuria results from a katabolic defect and most commonly arises from an absolute or relative deficiency of the internal secretion of the pancreas, although it may occasionally be produced by advanced destructive lesions of the liver. A partial differential diagnosis may be made by comparing the percentage of dextrin in a sample of urine passed after a fast of six or eight hours with the percentage in a specimen collected during the three or four hours following a mixed meal, but the result is at best only a rough guide and is not very dependable. A much more reliable opinion as to the cause of a pathological dextrinuria can be formed by estimating the percentage of hydrolysable carbohydrate ("difference value") and reducing sugar in the blood, fasting, and again at hourly intervals after a test-meal containing cooked starch. When the figures obtained in this way are plotted out three types of curve can be distinguished. In the first, or hepatic type (Fig. 1), the fasting values for the hydrolysable carbohydrate and reducing sugar are not abnormally high, in fact the sugar is usually low (80 mg. per cent. or less) ; after a meal the sugar

* *Special Copper Solution*, I. Copper sulphate 5 g., tartaric acid 7·5 g., pot. carbonate 59 g., distilled water 400 c.cm. II. Pot. iodide 10 g., pot. biniodate 0·7 g., pot. oxalate 18·4 g., distilled water 250 c.cm. Mix and make up to 1000 c.cm.

ncreases, although it may not reach the normal maximum, but the hydrolysable carbohydrate undergoes little change until the lapse of an hour or two, when it increases rapidly; by the fourth hour it may equal or exceed the reducing sugar in value. In the second, or primary pancreatic type (Fig. 2), the reducing sugar of the fasting blood stands at or above 100 mg. per cent., and the hydrolysable carbohydrate is considerably in excess of the normal average of 4 or 5 mg. per cent., the exact relation between the two depending upon the degree of pancreatic deficiency. After a meal the reducing sugar rises, perhaps to a pathological level, but the hydrolysable carbohydrate diminishes, and may temporarily disappear, to increase again as the percentage of sugar falls. In the third type (Fig. 3) the hydrolysable carbohydrate of the fasting blood is not excessive, but as the percentage of reducing sugar rises after a meal there is a corresponding increase in the hydrolysable carbohydrate, followed by a fall as the sugar returns towards the fasting level. Concurrent curves of this type appear to be associated with faulty glycogenosis arising from glandular and nervous disturbances interfering with the normal control of the pancreas over the process. Destructive lesions of the liver, of sufficient intensity to cause a pronounced rise in the hydrolysable carbohydrate of the fasting blood, can be distinguished from the similar increase due to primary pancreatic insufficiency by the level of the reducing sugar, which is subnormal with the former and normal, or above the normal, with the latter. Moreover, the clinical symptoms differ so widely that the two conditions are not likely to be confused. By carrying out these additional tests it is possible to form an opinion as to the immediate cause of a dextrinuria, and from the clinical symptoms, considered in conjunction with the results of other analyses of the blood, urine, and fæces, indications of the probable origin of the condition can often be obtained.

FIG. 1.

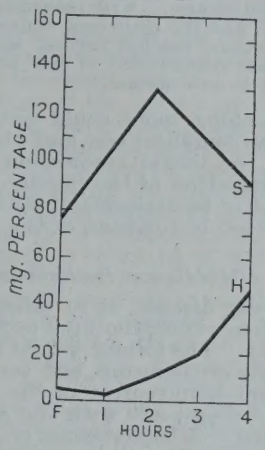

FIG. 2.

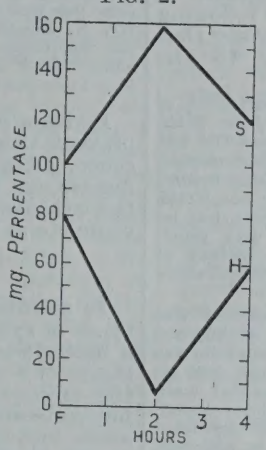

FIG. 3.

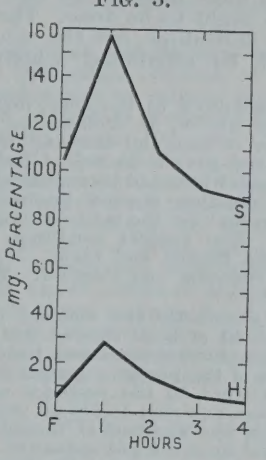

A lengthy experience of the methods of analysis I have described has afforded convincing evidence that they are of material assistance in the diagnosis of a variety of pathological conditions which it is otherwise difficult to differentiate with any degree of certainty. They are also of clinical value for another reason, and this is that they provide a means of discovering defects of carbohydrate metabolism at an earlier stage than any other at present available. The early diagnosis of pancreatic disturbances is particularly important, as they are liable to give rise to diabetes if allowed to progress unchecked. It is generally agreed that, if diseases of the pancreas causing deficiency of the internal secretion of the gland could be detected and dealt with in a pre-diabetic stage, the prospect of a permanent cure would be very considerably increased. I have found that dextrinuria invariably precedes the onset of glycosuria in such cases, often by months and sometimes by years, so that the discovery of its presence would seem to offer such an opportunity for commencing treatment before irreparable damage has been done. The early diagnosis of defects of carbohydrate metabolism due to relative deficiency of the internal secretion of the pancreas affords even better chances of instituting radical treatment than the discovery of an absolute deficiency, since persistent glycosuria develops only when the pancreas is exhausted and an actual deficiency of its internal secretion occurs. My observations on this type of case have shown that the characteristic concurrent curves of the hydrolysable carbohydrate and reducing sugar in the blood give place to the reversed curves of a primary pancreatic deficiency as the disease progresses, but that the concurrent curves reappear as improvement occurs under suitable treatment.

Dextrinuria arising from disturbances in the functions of the liver may apparently exist for many years without any definite signs of a diabetic condition developing, although the not infrequent presence of lævulose, pentose, and similar reducing substances in the urine occasionally leads to an incorrect diagnosis being made. In some instances I have seen alimentary glycosuria develop as a sequel of dextrinuria due to hepatic insufficiency, but always in people past middle life, and it is rather significant that alimentary dextrinuria may be found in one or more of the younger members of a family in which there is a history of glycosuria, usually of a mild type, occurring in old age.

PRESENTATION TO A MEDICAL MAN.—Dr. James Murray was recently entertained to dinner by doctors from Inverness and various parts of Ross-shire and Inverness-shire, to celebrate his jubilee as a general practitioner. Dr. J. W. Mackenzie presided, and Dr. John Macdonald, medical officer of health for Inverness town and county, proposed Dr. Murray's health, remarking in the course of his speech that he had been the first to introduce antiseptic surgical treatment in the Northern Infirmary. Dr. Murray, after being presented with a silver salver, described his good fortune in being closely associated with Lister as a prizeman and student in his class, and later on as house surgeon in Edinburgh Royal Infirmary under Sir Patrick Heron Watson. Dr. Murray graduated as M.B. in 1876 and as M.D. five years later. He went to Inverness in 1879.

OBSERVATIONS ON AURAL SYSTEMIC INFECTION.

BY ROBERT D. OWEN, B.SC. WALES, F.R.C.S. EDIN.,

LATE REGISTRAR AND CHIEF CLINICAL ASSISTANT, EAR, NOSE AND THROAT DEPARTMENT, GUY'S HOSPITAL.

IT is a well-recognised fact in otological practice that cases of aural systemic infection present most puzzling features, both in diagnosis and in treatment. The latter is made more difficult by the variety of opinion as to what ought to be done. The following case illustrates the difficulties, but the recovery that took place cannot be attributed wholly to the treatment.

A girl of 13 was admitted to the aural department of Guy's Hospital under Mr. W. M. Mollison on June 28th, 1927. She complained of pain and discharge from the left ear for seven days, and gave a history of feeling unwell, with headaches and pain which had become localised behind the left ear. Examination showed profuse non-fœtid discharge, and tenderness over the mastoid process, but no œdema or redness. Her general condition was good, although she appeared flushed and toxic. No history of shivering attacks or vomiting was obtained. Temperature was 102° F., pulse 84.

Under a general anæsthetic the mastoid process was exposed. Early removal of bone showed pus oozing out under pressure. When further bone was removed it was found that the limits of the posterior cranial fossa and its contents extended forward to the posterior meatal wall. The mastoid antrum was, however, deeply set, well developed, and full of pus. This was approached through the outer attic wall. The lateral sinus did not appear to be affected, being of good colour, soft, and smooth. There was no collection of pus in the "sinus groove." The upper half of the wound was closed, and a rubber drain inserted into the lower half.

On the 30th, two days later, there was a decided change in the patient. Her temperature rose to 105°, and respiration to 30; her lips were slightly cyanosed. She complained of vomiting and headaches, and at times became very restless and irrational. It was difficult to make a definite diagnosis. The absence of rigors somewhat disfavoured sinus thrombosis; the headaches, vomiting, restlessness, and temperature favoured meningitis, yet she had no neck rigidity or tenderness. A lumbar puncture was made, and a small amount of cerebro-spinal fluid was withdrawn; it was under pressure but clear. Direct examination showed many polymorphs, but not enough to cause turbidity. The lumbar puncture seemed to relieve her immediately of the headaches and restlessness. There were signs of bronchitis in both lungs.

The following day saw the disappearance of the headaches and restlessness, and there was still no neck rigidity. Her temperature was 104°, and although rigors were absent, the conclusion was that she was either suffering from sinus thrombosis or a generalised systemic infection secondary to mastoiditis. Under a local anæsthetic the internal jugular vein was ligatured and cut, but the sinus was left alone and not explored. At the same time blood was taken for culture, and 70 c.cm. of polyvalent antistreptococcus serum given intravenously. The following day her left knee-joint became markedly painful and tender. Examination of the urine showed albumin, blood, and pus cells. The blood culture gave a growth of *Streptococcus longus hœmolyticus*.

The clinical picture was now one of a generalised systemic infection, primarily of mastoiditis, with secondary nephritis, arthritis, and bronchitis. Another 70 c.cm. of antistreptococcal serum were given. This resulted in a severe rigor, the temperature reaching 105° and pulse-rate 150. The following day the temperature became normal, but reached 104° in the evening, so another 70 c.cm. of serum were given. This was again followed by a similar reaction, the temperature rising again to 104°.

The following day the patient was seen by Prof. J. W. H. Eyre, who gave her an injection of mercurochrome. Two days later another 10 c.cm. dose was given. The blood culture at this stage was negative, but the temperature kept on swinging between 100° and 104°.

On July 15th—i.e., 14 days later—on the advice of Dr. J. A. Ryle, her chest was aspirated, and 30 c.cm. of straw-coloured fluid were withdrawn, and two days later a similar amount was aspirated; yet her temperature remained high. Direct examination of the aspirated fluid showed many cells, 70 per cent. polymorphs, and 30 per cent. mononuclears, and many streptococci. Cultures gave a growth of hæmolytic streptococcus longus.

Blood picture about this date (third week after the operation): hæmoglobin, 53 per cent.; red cells, 2,920,000 per c.mm.; colour-index, 0·9; white cells, 9880 per c.mm.; polymorphs, 72·6 per cent.; lymphocytes, 18·6 per cent.; eosinophils, 0·6 per cent.; hyaline cells, 7 per cent. This picture gives a clear idea of the low state of her resistance and blood transfusion was discussed. It was, however, decided that it would be better to leave her alone. Her treatment therefore became limited to good nursing, nourishment, and sunshine. She appeared extraordinarily well mentally, and took a keen interest in everything.

On August 2nd—that is, 24 days after the first aspiration—her pulse-rate shot up to 150, and respiration to 35. On the advice of Dr. Ryle her right chest was aspirated; this time pus was withdrawn. A rib resection was performed by Mr. N. Echoff, and the empyema drained. The following day her temperature reached normal, and has remained so since. The last examination of her urine was negative. Her knee-joint is now normal.

Perhaps nothing more could have been done to prevent these complications and the long convalescence, after the initial eradication of the mastoid disease and resection of the jugular vein. Therefore the treatment of bacteriæmia of otitic origin is not as complete as that of toxæmia of the same origin.

Middle-ear Bacteriæmia.

In middle-ear disease, as in other conditions, two types of systemic infection may occur, a toxæmia or a bacteriæmia. The former can be seen in the early stages of acute otitis media, and can last throughout the subsequent involvement of the mastoid process, but generally disappears with the subsidence of the acute infection. A bacteriæmia, on the other hand, manifests itself when the primary disease in the mastoid process has spread to and into the venous blood channels. It is also evident when the initial mastoid disease is of the type characterised by primary involvement of the small blood-vessels—the typical clinical picture being that of the hæmorrhagic type of acute mastoid. The ototic systemic infections characterised by bacteriæmia can be produced in one of two ways, and there is no reason why the final treatment should differ. In the first variety the cellular elements in the mastoid process are subjected to the pressure of stagnant pus. A necrosis of the bony walls results, and produces the usual type of acute coalescent mastoiditis. By continuous pressure the sinus and dural plates can become necrosed from lack of blood-supply; this exposes the endocranium, which afterwards becomes the site of a perisinus or extradural abscess. Further continuous pressure causes injury to the endothelial lining of the sinus, and a thrombus develops. There is then present an infection of bacterial origin within the circulating blood; with the disintegration of the thrombotic mass this soon disseminates throughout the body and bacteriæmia results. This is the pathology of lateral sinus thrombosis, and the therapy in such a case is of two kinds, preventive and curative. Prevention is by timely surgical operation before the disease has reached and invaded the inner table. Once the systemic infection has become established, the curative treatment is the immediate removal of the septic thrombus in the blood channel and the obliteration of the route to the general circulation by ligation or resection of the internal jugular vein. If the systemic infection persists after these procedures the treatment of the infection per se can be considered, with the assurance that its source has been removed.

The other and more difficult type of mastoid disease which causes a systemic infection of bacterial nature is that characterised by the primary involvement of the small vessels in the mastoid process. It is caused generally by the hæmolytic streptococcus longus entering the lumina of the mucosal vessels. This results immediately in a multiplicity of infected thrombi; the infection, therefore, is located in the circulating venous blood, and not in the cell spaces. This does not cause destruction of the walls, because

they are not subjected to pressure necrosis. The disease is manifested by intense engorgement of the cell lining and by hæmorrhagic exudate into the cell spaces—hence the name of hæmorrhagic acute mastoiditis. From a clinical point of view, a systemic infection is present in the hæmorrhagic type from the beginning, and the disease itself is a systemic infection by virtue of its location within the blood stream—in other words, a venous thrombosis is present from the outset. The lesion in this case progresses by an intravenous growth of the thrombi towards the larger blood-vessels and not by the progression of a necrotic process. Consequently a perisinus abscess is rarely seen in this type of acute mastoiditis. The presence of bacteria in the blood stream does not depend on the presence of a septic clot in the lateral sinus, since particles of infected thrombi can be dislodged and find their way into the circulation as the small thrombi extend towards the larger vessels.

A determination of the extent of the thrombosis in this variety of hæmorrhagic mastoiditis cannot be made by mere inspection at the time of operation or by the subsequent course of the disease, since the sinus itself is invaded by the intravenous extension of the thrombi into its lumen. Therefore one must not look for the same indications for lateral sinus and jugular surgery in this type of mastoiditis as are found in the coalescent type. Early operation in these cases generally succeeds in eradicating all the infected thrombi in the mastoid venules, and this generally prevents further extension of the infection into the sinus. When the ordinary mastoidectomy proves sufficient to end the disease, the sepsis stops at once. On the other hand, where surgery fails to remove the thrombi, the sepsis continues, and there is a progressive diminution in the hæmoglobin and red cells, as in the case described.

H. Kerrison remarks that the blood picture furnishes a most valuable guide to the extent of the thrombosis; where, after simple mastoidectomy, the sepsis and the reduction in hæmoglobin and red cells continue, it shows that the larger blood exits are involved and is, therefore, an indication for opening the sinus and tying the jugular vein.

The Place of Blood Transfusion.

When, after this procedure, the anæmia becomes more marked, H. Hays maintains that blood transfusion is the best therapeutic agent. The hæmolytic organism in the blood destroys the hæmoglobin, and the resulting marked anæmia permits the bacteria to overcome the patient's resistance. J. McKernan remarks that in the differential blood count a high polymorph percentage without a proportionately high total white count gives an indication that the infection is gaining control over the body. Hays also maintains that there are no contra-indications to blood transfusion, properly given, for toxæmias and infections. The transfusion is used to replace lost hæmoglobin and red cells, and not to furnish antibodies, though the latter is valuable where it occurs. Transfusion ought to supply the best method of treating these cases of generalised infection after the operation to remove the septic focus in the temporal bone has been performed.

The other point of treatment that needs emphasis is that a case with aural discharge and symptoms of generalised infection with a positive blood culture warrants the performance of sinus and jugular surgery. It has been proved that in these cases there is always thrombosis. L. Libman, in 1908, showed that sinus thrombosis and meningitis are the only otitic complications giving rise to general bacteriæmia.

I am indebted to Mr. Mollison for permission to operate and publish the details of the above case, and for his valuable help. Also to Mr. R. Jarman, the house surgeon, for his untiring efforts in seeing to the details of the treatment.

Clinical and Laboratory Notes.

NOTE ON THE EFFECT OF ANÆSTHETICS ON BLOOD IODINE.

BY W. ANDERSON, O.B.E., M.B. ABERD., F.R.C.S. ENG. & EDIN.,
ROYAL INFIRMARY, ABERDEEN;
AND
I. LEITCH, M.A., D.SC.
(*From the Rowett Research Institute, Aberdeen.*)

THE fact that anæsthetics may have a marked effect on the iodine content of the blood was first noted accidentally in rabbits killed with chloroform. The blood of rabbits normally has an iodine content of from 10γ to 15γ per 100 c.cm.[1] In the blood sampled immediately after death under chloroform only a trace of iodine was found. Following this discovery a few experiments were done on goats with administration of chloroform or ether, the blood being sampled before and after the anæsthetic; samples of human blood were also taken before and after operations under different anæsthetics. Iodine estimations on these samples have shown that in some cases a very marked rise or fall in blood iodine occurs, a fall usually occurring under chloroform and a rise under ether. The table summarises the results.

—* = Before anæsthetic. † Cocaine and adrenalin.
C. & E. = Chloride and ether. G. & O. = Gas and oxygen.

[1] γ = 0·000001 gramme.

The results are not altogether uniform, and possible complications are involved in these preliminary observations from the simultaneous administration in some cases of adrenalin. It has already been shown by Veil and Sturm [2] that adrenalin raises blood iodine. The observations appear, however, to be of some clinical importance, and the investigation is being continued.

In these preliminary observations there are indications that the age and sex of the patient and the nature of the disease may affect the level of blood iodine. In the further work to be done account will be taken of the possible influence of these factors.

CONCURRENT APPENDICITIS AND MECKEL'S DIVERTICULITIS.

BY ALEX. CUMMING, M.B. N.Z.,
RESIDENT SURGICAL OFFICER, NORTH ORMESBY HOSPITAL.

ALTHOUGH the signs of appendicitis closely resemble those of Meckel's diverticulitis, and the one condition is often confused with the other, their simultaneous occurrence has seldom been recorded.

A boy of 9 was admitted into hospital on May 26th, 1927, with the usual signs of acute appendicitis. A cœliotomy was performed by the gridiron incision, and the appendix was removed. It was swollen and inflamed, and its distal half was surrounded by some pus. A small drain was inserted, and for the ensuing seven days the progress, though slow, appeared satisfactory. On June 3rd his abdomen was tumid, and later he began to vomit fæculent material. A secondary obstruction was diagnosed, and the abdomen was opened in the mid-line. The cavity was full of fæcal-smelling pus. A Meckel's diverticulum, about 2 inches long, was found on the border of the ileum, to the right of the mid-line. The diverticulum was perforated at its base, but its distal end was free and did not share to any extent in the inflammation. The base was not constricted, nor was the ileum. The diverticulum was removed, and the perforation was sutured without causing any narrowing of the bowel. The patient recovered without further interruption.

Ulceration at the base of the diverticulum is known to be a cause of narrowing of the adjacent segment of bowel, but perforation there is an uncommon sequel.

A CASE OF ERECTION OF THE VERMIFORM APPENDIX.

BY S. A. LANE, M.D. DUB.,
SURGEON, BOGNOR WAR MEMORIAL HOSPITAL.

THE following case seems sufficiently interesting to record.

The patient, a female aged 30, was admitted to hospital with a diagnosis of acute appendicitis. An emergency operation was carried out, the abdomen being opened by a right paramedian incision. When the parietal peritoneum was opened the appendix, turgid, hard, and much thickened, rose slowly from the wound with its mesentery dependent from it, looking like the style on a sun-dial.

The cause of this surprising condition was found to be an extremely acute kink at the base of the appendix. On releasing the kink the condition at once subsided, leaving an appendix to all appearances normal.

As the whole length of the appendix appeared to be equally affected, it is probable that the entire vascular supply was derived from the cæcal vessels, which would favour hæmorrhage into the bowel unless an efficient ligature were put on the cæcum. In my experience catgut has proved unreliable in this situation. The ligature embraces the wall of the cæcum and not the base or "stump" of the appendix. The effect of a purse-string suture is to cause inversion from the peritoneal aspect, but there is a distinct possibility of eversion towards the cæcal lumen, and consequent slipping of a catgut ligature with its relatively inefficient "bite."

Several cases have been reported of severe hæmorrhage which could not have occurred had a reliable ligature been employed in this situation.

[2] Veil and Sturm: Deut. Arch. f. Klin. Med., 1925, cxlvii., 166.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

AT a meeting held at Dublin on Nov. 18th Mr. ANDREW FULLERTON, the President, read a paper on the

TREATMENT OF ENLARGED PROSTATE.

As a general rule, he said, a patient did not seek relief for the symptoms of enlarged prostate before the age of 55–60. It was, however, a mistake to suppose that enlargement of the prostate was never a cause of urinary symptoms in men under 50 years, as was illustrated by several cases of his own in men as young as 45 and 47. The symptoms of the condition might be various. There might be frequency by day and not by night, or incontinence (due to the irregular shape of the urethra), or bladder distension without any trouble with micturition. He was often asked by patients, "Can I, with a reasonable degree of safety, postpone what I know is an inevitable operation for a few months, or a year or two?" The answer to this question, given careful supervision, was a "qualified affirmative"; it depended upon the patient's general health and the effect of obstruction on the kidneys. The President attached the greatest importance to a daily record of the amount of urine and of its specific gravity, both of which might be reported by the patient. Any evidence of failing health, or an increasing total quantity or progressive fall in specific gravity of the urine, indicated the necessity for reinvestigation. The advent of sepsis in the bladder was a serious complication and micro-organisms were likely to multiply in spite of frequent irrigation. To render his condition more comfortable, the patient should regulate his fluids, avoid alcohol, tea, coffee, or highly spiced foods, and anticipate the urgent desire to micturate. Owing to spasm occurring simultaneously with the desire to micturate, the bladder was often imperfectly emptied, but if the patient resumed micturition some five or ten minutes afterwards more urine could be passed owing to the spasm having lessened, and the process might, with advantage, be again repeated. This might be termed "divided micturition," and was distinctly helpful because it gave longer periods of sleep at night. The influence of spasm in causing difficulty of starting the act of micturition was shown by the fact that morphia gr. 1/6 and atropine gr. 1/180 would get over this difficulty for 24 hours.

In preparing cases of chronic uræmia for operation, continued the President, the tied-in catheter was preferable to regular catheterisation. Suprapubic cystotomy should be reserved for the rare cases which failed to improve with the in-dwelling catheter. Sepsis, in all cases where an in-dwelling catheter was used, was controlled by washing out the bladder daily with permanganate of potash or nitrate of silver. Evidence of the superiority of the tied-in catheter over catheterisation was shown in two cases in which the blood-urea fell from 146 to 40 mg. and 102 to 42 mg. per 100 c.cm. respectively. The President added to the technique of suprapubic prostatectomy—the operation most often performed in this country—by stretching or cutting the posterior lip of the septum between the cavity vacated by the prostate and the bladder; this, he said, obviated a common complication—namely, the formation of a diaphragm between the cavities. Enucleation could be easily done with the gloved finger. If packing was necessary, he advocated the use of an aseptic marine sponge in lieu of gauze. The Pilcher bag tended, in his experience, to stretch the external sphincter unduly. Slight incontinence had persisted to a mild degree in one case following its use. Referring briefly to deep X ray therapy, still in its experimental stage, he said that while he had seen some relief from this method his experience was limited.

The most difficult problem to be encountered in the after-treatment of enlarged prostate, said the President in conclusion, was that of sepsis. Irrigation, which had been carried out successfully in many cases, had got rid of the sloughs and cleansed the bladder, but it had sometimes been the means of lighting up infection. Any interference with the suprapubic wound was very dangerous. Its closure was often attended with a rigor, and at such a time irrigation was fraught with risk. Infection of the perivesical space was less likely to occur if care was taken to avoid undue opening of the space of Retzius. Should infection occur, adequate drainage ought to be provided.

Discussion.

Mr. R. C. B. MAUNSELL thought that the most anxious time in prostate cases was when the surgeon did not want to operate on them, when the patients came with symptoms of early prostatic disease. It was hard to know how long these cases could safely be left without operation. What percentage of risk was there of what seemed to be a simple enlargement becoming malignant? He had not got such good results from the use of an in-dwelling catheter as he had from suprapubic drainage, and he thought that the latter was the better method of preparing the patient for operation, as it made removal safer and reduced the bleeding. Also, some patients who had had an in-dwelling catheter, refused to have it taken out, and were inclined to refuse to be operated on, even though the surgeon might have made up his mind that an operation was necessary. If suprapubic drainage was employed, he did not think it likely that patients would refuse operation. He had found that the best thing in prostatic treatment was washing out. If washing out was done regularly in 12 or 14 days after operation there would be no sloughs, and in from 14 to 21 days the wound would be healed up. Washing out should be done every third day after operation. He personally used 1 in 10,000 silver nitrate.

Mr. L. G. GUNN expressed disapproval of the two-stage operation, which he would never perform. He just used a catheter as required. He had had a great deal of experience of X ray treatment, and thought it was beneficial when the gland was of the soft adenomatous type. In his experience very few cases of this type had had to be operated on after X ray treatment. If, however, the gland was smallish and fibrous, he did not think that X rays were efficacious at all. He had not had much experience of deep X ray therapy, but had seen two cases in which it had caused stricture of the ureters. It did not matter, he thought, how much fluid the patient took; it depended more on nervousness than on the intake of fluid what amount of urine was passed. A gloved finger was not, he considered, an advantage to the surgeon, and was a disadvantage to the patient. As regards the question of sloughing after operation and washing out the bladder, he thought that it depended on whether it had been necessary to use much force in taking out the prostate. He very seldom irrigated, but gave large doses of urotropin. Once a patient began to pass water himself washing out was unnecessary. He took out the gauze packing at the end of the 48 hours.

Mr. SETON PRINGLE had found that in nine cases out of ten renal function was deficient when the patient came to him, and some method of preparation for operation was necessary. He personally did suprapubic cystoscopy and he did not use the in-dwelling catheter. Some patients suffered from incontinence for about eight days after the tube was removed. After operation he put in a large drainage-tube which was taken out after two days, a small tube being inserted in the bladder. This was left in for about ten days, and then removed, and the patient was encouraged to pass water. He hardly ever irrigated. It was important, he thought, to remember that the openings of the ureters were patent, and that distension of the bladder after operation might quite easily force infection up into the ureters. He had had no fatalities from deep X ray therapy, and some cases had done very well after the treatment, but it was, of course, still in the experimental stage.

Mr. J. L. KEEGAN had found the use of the self-retaining catheter before operation most successful. If the bladder was thoroughly exposed it was quite easy to enucleate the prostate with a gloved finger.

Mr. D. KENNEDY said he had wondered, when the operation was carried out on a healthy bladder, where the sepsis came from. He had found that in all cases sepsis after the operation came from the suprapubic wound. This he thought was due either to bad operative treatment or to bad nursing. He always tried in these cases to have a special nurse, so that the dressings might be changed frequently, as he thought that if the abdominal wound was kept thoroughly clean there would be little or no sepsis and no sloughing. Once decomposed urine could be smelt there was a danger of sepsis. The important thing was to keep the abdominal wound aseptic. After operation he gave urotropin, and changed the dressing every two hours.

Mr. R. A. STONEY asked if the President had used a spinal anæsthetic in any cases. He himself had used one several times, and had been very pleased with the result. It seemed to lessen the tendency to bleeding, and caused perfect relaxation of the abdominal muscles, thus making it much easier to work inside the bladder. It also rendered convalescence quicker.

Mr. H. STOKES thought that there were certain patients who suffered from retention, and on whom it was not possible to operate, who, nevertheless, recovered and led perfectly happy lives. He mentioned two patients of his who, after catheterisation for three weeks, got all right, and now passed urine without difficulty.

Mr. V. J. MCALLISTER said that in some cases drainage by catheter was unsuitable. Where there were indications for a two-stage operation it was necessary to fall back on preliminary cystotomy. In the majority of cases, he thought, preliminary treatment was needed. He asked the President what percentage of cases might be classified as good risks, bad risks, and fair risks. He himself considered that about 40 per cent. might be classified as good risks, and the remainder divided between bad risks and fair risks. He had recently been trying the creatinin test and the phenolphthalein test, and though he could not make up his mind which was the better, he thought that the creatinin was the more reliable of the two. If the blood-urea was more than 60 mg. per 100 c.cm. he thought that operation for removal of the prostate should not be undertaken. He had often found that patients were more upset by the preliminary cystotomy than they were by the actual prostatectomy. When the patient seemed ill he thought that it was better to empty the bladder for a few days by continuous or by intermittent drainage before preliminary cystotomy. Regarding the perineal operation, he said that there was a danger of injuring the rectum, and of getting a certain amount of incontinence afterwards. He also had found spinal anæsthesia good. He asked what should be regarded as a fair mortality. He personally thought that if 60 per cent. of good results were obtained, and if 75 per cent. were relieved, that surgeons would be doing well.

The President's Reply.

The President said that he had had very few cases in which, with a long history of prostatic disease, malignancy had occurred. He believed that in the large majority of malignant cases the condition was malignant from the beginning. He very seldom took more than three minutes to do a prostatectomy, and he could do the operation much quicker if he had an abdomen which had not been interfered with in any way. He could not agree that if the operation was done with a gloved finger there would be more sloughing; he thought that having a gloved finger had several advantages over performing the operation with a bared finger. He sometimes washed out

through the urethra and sometimes through the suprapubic wound. Treatment by X rays was certainly more effective when the adenoma was soft. He had heard of some cases in which sclerosis of the ureters had occurred after X ray treatment, and this, of course, was a terrible disaster. He thought that packing with gauze often defeated its own end. He had found that no matter what precautions were taken the wound would slough. Even with every care it was impossible to avoid wounds becoming septic, and he thought that a bladder which retained urine could never be rendered aseptic, even after operation. He had had a mortality of 7·4 per cent. In four London hospitals he believed that the mortality was about 15 per cent. As an anæsthetic he thought that gas and oxygen was the best of all in these cases; he never used ether, and did not care for chloroform. It was difficult to say what the percentage of fair risks was, as a great deal depended on the treatment that was given. The results of prostatectomy were good. The test which gave the best results was, in his opinion, the estimation of blood-urea considered in relation to the patient's appearance. Cystotomy had a definite mortality attached to it.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON Nov. 29th Dr. EDMUND SPRIGGS read a paper on

Early Symptoms of Cancer of the Stomach.

He said that study of the early symptoms in a series of patients showed that the onset of the disease was appreciable in most cases. In two-thirds of them the symptoms had dated back more than nine months, and on the average an interval of a year or more had elapsed before a full investigation was made. An analysis of the symptoms in order of frequency, and of the order in which they arose, showed that the most important early symptoms were fullness and discomfort or pain, not severe or continuous, but recurring persistently, and arising in a middle-aged or elderly person. The next in order of frequency and importance were lack of appetite, dislike of food, or nausea, with resulting loss of weight. Hæmorrhage might be the first symptom. The pain or discomfort was often relieved by food in cancer of the pylorus and of the body of the stomach. Of the cardinal symptoms of cancer wasting and tumour were late results, and pain was so variable that no security could be assumed from its absence. Anæmia was usual, though, in exceptional cases, the blood might be normal until shortly before death. When cancer arose in the subject of ulcer or other forms of dyspepsia there was often a recognisable change in the symptoms. The earliest objective sign of cancer was probably local arrest of the wave in the stomach as shown by X rays. This was demonstrated by the superposition of serial films taken at such an angle that the lesion was in profile, and the sign was common to cancer, ulcer and fixation by adhesions. Cancer was suggested by a filling defect, or much induration at the edge of an ulcer, as shown by bending over of the shadow. The tests for achylia and occult blood were of great value.

If there was radiological and clinical suspicions of cancer, said Dr. Spriggs, the risk of operation to make sure was much smaller than the risk of watching the case. It was wrong to treat indigestion for any length of time in a middle-aged person without taking steps to exclude cancer. Resection of the pylorus or the body of the stomach, if undertaken at an early stage, could be performed successfully. The fight against cancer was a fight for early diagnosis. If the delay between the onset of symptoms and investigation could be avoided life could be saved in a great proportion of cases. Further progress depended at present upon the profession and the public becoming alive to the fact that earlier diagnosis could and should be made.

Reviews and Notices of Books.

BACTERIOLOGY AND SURGERY OF CHRONIC ARTHRITIS AND RHEUMATISM.

By H. WARREN CROWE, D.M., B.Ch. Oxf., M.R.C.S., L.R.C.P. London: Humphrey Milford, Oxford University Press 1927. Pp. 197. 30*s*.

THIS book, which is essentially original and personal, consists of four main parts: (1) a plea that osteo-arthritis is the result of chronic infection with streptococci, and the presentation of certain evidence for this; (2) the thesis that rheumatoid arthritis is a chronic articular infection with a variety of staphylococcus; (3) a chapter on the use of vaccines in these conditions, with a résumé of their surgical treatment, contributed by Dr. H. Frankling; (4) an essay upon the classification of streptococci. The result is somewhat incoherent, and is made to appear more so by an appendix upon the daily weight chart as a guide to tuberculin, which hardly seems relevant.

Dr. Crowe finds evidence for streptococci as the cause of osteo-arthritis and non-articular rheumatism in three directions—animal experiment, focal infection, and serological observations. "Such evidence as is afforded by the successful result of treatment is not," he writes, "here invoked. It is always suspect." Nevertheless he frequently makes references to treatment to support his argument. The evidence from animal experiment is unconvincing. As regards focal infections, especially root infections of teeth, the evidence as to their existence is, of course, overwhelming, but the critical link between these and the arthritic conditions is as weak as ever. Dr. Crowe devotes a chapter to the consideration of a book by Dr. Weston A. Price upon similar subjects; but he remarks that "the only part of Dr. Weston Price's work which up to now has fallen within my particular experience . . . is the bacteriology. This, I think, is open to a great deal of criticism," and he subjects the work to destructive analysis. It is difficult to follow Dr. Crowe here, for he stresses repeatedly the number and variety of types of streptococci which may be isolated from the roots of infected teeth, but does not indicate precisely his own position with regard to their ætiological importance. We gather that on the whole he thinks any or all of them may be the cause of the osteo-arthritis, in which case classification rather loses its importance in this respect.

Rheumatoid arthritis is claimed to be due to staphylococci, either to a yellow chromogenic variety or to the *Micrococcus deformans* of the author, which is to be distinguished from the ordinary *Staphylococcus epidermidis albus* by its lesser activity in clotting milk and a slight morphological difference in colony form. These cocci he finds in the scurf and urine of his cases and, in four instances, he has isolated those of the second type from joints. In the section dealing with streptococcal classification the author puts forward an entirely new basis, depending upon the appearances of colonies growing on a specially prepared "chocolate" medium. He defines 27 major groups, each with a number of described or yet to be described constituents, based upon characters which he tells us are not constant in subculture. Time will show if this classification has practical value; if it has bacteriologists must needs feel grateful, if chastened.

Dr. Crowe is to be congratulated upon the excellence of his photographs and of the colour process reproductions.

A TREATISE ON ORTHOPÆDIC SURGERY.

Eighth edition. By ROYAL WHITMAN, M.D., M.R.C.S., F.A.C.S., Surgeon to the Hospital for the Ruptured and Crippled, New York. London: Henry Kimpton. 1927. With 954 engravings. Pp. 1061+xii. 45*s*.

THE short intervals between the appearances of successive additions of Dr. Royal Whitman's standard text-book provide eloquent testimony to the popularity

of the work and to the steady demand for it among English-speaking practitioners. Only three years have passed since the seventh edition appeared, which succeeded the sixth after five years. The greater part of the book remains unchanged, but there are nearly seventy more pages and over seventy more illustrations. The greater part of the new matter consists of descriptions and illustrations of operations which have been introduced since the publication of the seventh edition, but besides this there are new paragraphs on myositis ossificans, fracture of the carpal bones, Kienbock's disease, and what Prof. F. W. Wood Jones has called "trick movements" in paralysed limbs. The section on collateral orthopædic surgery remains as in the last edition, with the addition of quotations from Kovac describing the use of physiotherapeutic measures, including various forms of light and heat. Such changes as have been made in the book increase its value.

APPLIED ANATOMY.

Seventh edition. By GWILYM G. DAVIS, M.D., late Professor of Orthopædic Surgery and Associate Professor of Applied Anatomy in the University of Pennsylvania. Revised by GEORGE P. MÜLLER, M.D., Professor of Clinical Surgery in the University of Pennsylvania. London: J. B. Lippincott Company. Pp. 638. 42*s*.

IN this edition of the late Dr. Davis's well-known work the original plan has been retained though the book has been subjected to a thorough revision. Most of the additions have been made in the descriptions of modern surgical procedure, though much new anatomical matter has been introduced. The 350 illustrations by Mr. Erwin F. Faber are uniformly good, and the volume as a whole can be thoroughly recommended.

OPHTHALMOLOGY.

An Introductory Course in Ophthalmic Optics. By ALFRED COWAN, M.D., Assistant Professor of Ophthalmology in the Graduate School of Medicine, Pennsylvania. Philadelphia: F. A. Davis Company. 1927. With 121 illustrations. Pp. 262. 15*s*.

THIS book is meant to convey to the student a good working knowledge of ophthalmic optics without demanding more than an elementary knowledge of mathematics. The laws of refraction, the properties of lenses, and the dioptric system of the eye are the subjects of the earlier chapters. There follow sections on the refractive conditions usually found and a concluding chapter deals with the use of the ophthalmoscope and retinoscope. Only simple typical cases are given. The book will be found useful by those for whom it is intended.

Ophthalmoscopy, Retinoscopy, and Refraction. Second edition, revised and enlarged by W. A. FISHER, M.D., F.A.C.S., Professor of Ophthalmology, Chicago Eye, Ear, Nose and Throat College. Same publishers. 1927. With 260 illustrations, including 48 coloured plates. Pp. 291. 16*s*.

THIS book is written with the avowed object of enabling the general practitioner to correct the common errors of refraction and to become proficient in the use of the ophthalmoscope. The bulk of the book is elementary but a new chapter by R. von der Heydt has been added to the present edition touching on the newer methods of refinement in ophthalmic diagnosis. These methods include the red-free light of Vogt, the Gullstrand binocular ophthalmoscope and microscopy of the living eye by slit-lamp illumination. We have no fault to find with the information given in the book so far as it goes, but it does not go very far. The whole subject of squint, for instance, is omitted. The matter included is, moreover, available in many ophthalmic text-books of modest dimensions. Perhaps the best part of the book is the inclusion of 24 plates of typical ophthalmoscopic appearances which, it is suggested, should be studied by means of an artificial schematic eye. Why these plates should all be printed in duplicate is not clear. Since a second edition has been called for, the demand for such a work as this must be considerable. It fulfils the purpose for which it has been written adequately; but it should not be forgotten that anyone who sets out to prescribe glasses for simple cases without having a sound working knowledge of the diseases of the eye as a whole runs grave risks.

MORBID HISTOLOGY.

Atlas der Histotopographie gesunder und erkrankter Organe. Von Dr. ERWEN CHRISTELLER, Direktor der pathologisch-anatomischen Abteilung des städtishen Rudolf Virchow-Krankenhauses in Berlin. Leipzig: Georg Thieme. 1927. With 182 colour photographs. Pp. 89. M. 90.

THE assumption that morbid histology has served its purpose and no longer plays an active part in pathology is inexplicable to those who realise the true value of the subject. A knowledge of structure, both normal and abnormal, must be the basis of pathology, and, after all, the microscope only enables us to appreciate the finer details of structure which we cannot distinguish with the naked eye. It would be more reasonable to divide doctors into those who wear spectacles and those who do not, than it is to recognise some who can use a microscope and some who cannot.

Dr. Christeller's atlas serves most admirably to bridge the gap between those who are satisfied with their unaided vision and those who like to see a little more. It consists of nearly 200 reproductions in colour of stained sections of whole organs or masses of tissue—the magnification of the majority of the sections is about 1·5, though some are little higher. The figures demonstrate the anatomical effects of various lesions in a way which neither the naked eye specimen nor the ordinary microscopic section can possibly do; and their value is greatly enhanced by the clear and brief descriptions which accompany them. The book is admirably got up, and though the price will put it beyond the reach of most students, it should find a place in the library of every teaching institution.

A TEXT-BOOK OF HISTOLOGY.

Fourth edition. By HARVEY ERNEST JORDAN, A.M., Ph.D., Professor of Histology and Embryology, University of Virginia. London and New York: D. Appleton and Co. 1927. Pp. 857. 25*s*.

FEW alterations have been made in the preparation of the fourth edition of this text-book. The most notable addition consists of a short account of the reticulo-endothelial system, but evidently reluctance to disturb the setting of the volume has caused this section to be unduly condensed. Other additions, of which there are about 12 in number, are mostly in the form of footnotes. In the chapter on blood the author has adopted the simpler term monocytes to embrace the large mononuclears and transitionals of the older terminology. Amongst the illustrations a few changes have been made with good effect. One photomicrograph of the older editions has been replaced by a drawing; others still demand critical attention.

In the preparation of his text-book Prof. Jordan has kept foremost in his mind the needs of advanced medical students, and he has produced a work of great academic value. The study of development, function, and the interrelationship of tissues and organs is applied in such a way as to impress clearly on the mind of the reader the most important peculiarities of histological structure. One need of the average medical student has, however, not been

taken into much account—the need for brevity. The time set aside for any subject in the medical curriculum is short; the fact that most modern text-books are large works lays a heavy burden of responsibility on the teacher, for the student cannot without help discover the essentials of any subject.

This book is admirably suited to the advanced science student and to the laboratory worker.

RONTGEN TOPOGRAPHY.

An X Ray Atlas of the Normal and Abnormal Structures of the Body. Second edition, revised and enlarged. By ARCHIBALD MCKENDRICK, F.R.C.S. Edin., D.P.H., F.R.S.E., and CHARLES R. WHITTAKER, F.R.C.S. Edin., F.R.S.E. Edinburgh: E. and S. Livingstone. 1927. With 448 figures. Pp. 256. 30*s.*

EVEN those who are prejudiced against atlases, on the ground that they seem to infer that radiology can be learned by the study of a series of pictures, must be impressed with the value of this volume to those who have not the rich experience that is enshrined therein. The atlas in its revised form has been enhanced by the addition of 60 illustrations. We still find conspicuous gaps, as, for instance, in the small range of illustrations of thoracic and œsophageal conditions. In the first edition there was an appendix of nearly 30 miscellaneous radiographs. This arrangement has not been altered; yet there are very few of these illustrations that could not have been redistributed into their appropriate sections. The Basle nomenclature is used throughout—this is unfortunate, since this drastic, disturbing break in traditional nomenclature has already been largely abandoned.

The high level of publishing art which was so strong a feature in the first edition is fully maintained, and the publishers are again to be congratulated on the very excellent way in which the volume is produced.

PARTURITION IN ANIMALS.

Biologie und Pathologie der Schwangerschaft und Geburt bei den Haussäugetieren. By Prof. Dr. med. vet. KARL KELLER, Veterinary High School, Vienna. Berlin and Vienna: Urban und Schwarzenberg. 1927. Pp. 815–966. M.8.

THIS treatise, which forms the third part of Volume VIII. of the encyclopædic *Biologie und Pathologie des Weibes*, edited by J. Hakban and L. Seitz, is an attempt to show that the veterinary clinic may furnish many observations and experiences useful to gynæcologists. Author and editors share the view that in these days it will be to the advantage of human and animal medicine if as many bridges as possible are built between them. The field of animal medicine is briefly surveyed, the species dealt with including the mare, cow, goat, ewe, sow, bitch, and cat. The bibliography is one-sided. Only two British workers are referred to, and the work of Stockman on abortion (p. 876) is erroneously attributed to America. The illustrations, of which there are 62, are excellent, especially the coloured plate showing the lesions caused by *B. abortus* Bang.

CHILD PSYCHOLOGY.

Everyday Problems of the Everyday Child. By DOUGLAS A. THOM, M.D., Instructor in Psychiatry, Harvard Medical School. London and New York: D. Appleton and Co. 1927. Pp. 350. 10*s.* 6*d.*

THE number of volumes which have appeared during the last few years on various aspects of child psychology has been so large as to suggest a state of over-production in this branch of literature. This book, however, compares so advantageously with a great number of its kind that its publication is fully justified. It has the great merit of maintaining a scientific and unemotional outlook, not too closely adherent to any particular school of thought. Controversial questions, such as the relative preponderance of hereditary and environmental factors, are presented in a fair and well-balanced manner, while the greater part of the book is devoted to accounts of individual cases drawn from the author's large experience, and to an extremely lucid and practical discussion of the problems which they exemplify. The importance of keeping constantly in mind the physical condition of the child who exhibits disturbances of behaviour receives more recognition than in many other works of this kind. Practitioners, as well as parents and teachers, will find much in this book which will assist them in the prevention and treatment of neurosis in childhood and in the management of the "difficult" child.

SEX AND REPRESSION IN SAVAGE SOCIETY.

By BRONISLAW MALINOWSKI, D.Sc. London: Kegan Paul. 1927. Pp. 285. 10*s.* 6*d.*

Dr. Malinowski has studied at first hand savage communities in the Pacific, and now examines those theories of psycho-analysis, built upon the discovery of the Œdipus complex, which assume that nuclear complex to be universal and responsible for the development of myth and fairy tale, of savage customs, and the forms of social organisation as well as the achievements of material culture. He takes the view that the complex is not the cause of sociological structure but the effect, and uses his studies of a predominantly matrilineal system, as existing among the Trobriand Islanders, to demonstrate that in its presence the complex fails to show itself in characteristic form. The Œdipus complex depends, we learn from the author, upon the incorporation in the father of the two functions of tender friend and rigid guardian of law. Among the Trobrianders these functions are separated; the father is only a friend of the family, whilst authority is represented by the mother's brother, so that the child is not called upon to harmonise the two functions in one person. Among them, too, sex repression in the education of the young—emphasised in many primitive people as well as in our own civilisation—is entirely absent. To this fact he ascribes the absence of perversions and the open and accessible nature of the natives of the Trobriands when compared with those of neighbouring islands. There is, however, a powerful taboo set up between sister and brother, and he shows that their traditions and myths are built up on this taboo.

Dr. Malinowski's arguments against Freud's hypotheses of the primitive horde and totemic parricide as the origins of the Œdipus complex are cogent, and show no trace of any aim other than the search for scientific truth. He more than once makes a plea against, on the one side, the lack of collaboration of psycho-analysts with other workers and, on the other, the ignorance of specialists concerning what is without doubt an important contribution to psychology. Shand's theory of sentiments, for example, stands in a very close relation to psycho-analysis, but the nature of the reception accorded to the new teaching has excluded an examination of the relationship.

The book has its practical interest for those who approach the psychoneuroses as difficulties in social or family adaptation. How anthropological and clinical studies converge is well expressed by the author when he writes (p. 276): "And many maladjustments within the mind and in society can be traced back to the faulty cultural mechanism by which sexuality is suppressed and regulated or by which authority is imposed." The uninformed reader might perhaps receive the impression that the hypothesis of the primitive horde is an integral part of psycho-analytical theory instead of a deduction from observations that are accepted by many people, including Dr. Malinowski. This was not the intention of the author, but it must be mentioned because the book, whilst thoroughly scientific in the handling of its subject, makes otherwise no demands upon previous knowledge of more than a general kind.

THE LANCET.

LONDON: SATURDAY, DECEMBER 31, 1927.

SIR DAWSON WILLIAMS.

LAST week it was announced that the Council of the British Medical Association had received from Sir DAWSON WILLIAMS his resignation of the editorship of the *British Medical Journal*. The resignation will take effect in January, 1928, on the date at which Sir DAWSON will have completed his thirtieth year as editor, while he had been connected previously with the editorial department of the paper for some 17 years, during most of which time he held the post of assistant editor. We can well understand the deep regret with which the body of the Association generally, as well as every one in its official departments, will have learned the announcement. We share the regret, and the more completely because, in the conduct of *The Lancet*, the relations between this paper and Sir DAWSON WILLIAMS, throughout his editorship of the *British Medical Journal*, have been necessarily of an intimate character, and thus we know how inestimable in value his life-work has been, not only to the Association but to the cause of medicine generally during his long tenure of the editorial chair. We are in a position of peculiar ability to gauge the statesmanship, the patience, and the courage displayed by him in many positions of difficulty and delicacy throughout a period of revolutionary changes in our science, our art, and our everyday machinery, every one of which changes has been reflected in the labours of the British Medical Association; and we are expressing the opinion of all when we point to him not only as the mainstay of the Association throughout his extended term of service but as a great champion of our profession. For in the British Medical Association, as must happen in all corporations, presidents and councils arrive, discharge their functions, and are succeeded in due course by others; but this long official roll has enjoyed for 30 years the guidance of one whose views have never declined from their high standard, while his experience, as it was perfected year by year, has been at the disposal of the Association for the profit of all.

The post vacated by Sir DAWSON WILLIAMS has been offered to and accepted by Dr. NORMAN GERALD HORNER, who has been for 11 years assistant editor of the *British Medical Journal*, and who, we are glad to remember, served *The Lancet* previously for some time in a similar capacity. We wish Dr. HORNER all success in bearing his burden of responsibility, and have every reason for knowing that the wish will be fulfilled.

THE PREVENTION OF PARATYPHOID.

ENTERIC fever of the old type with a high fatality seems to have almost disappeared. Outbreaks of paratyphoid, however, are fairly often reported, and two recent epidemics, both traced to milk, give occasion for thought. In West Hertfordshire there were about 150 cases, mostly in the first half of November. The dairy involved was supplied by nine farms, at one of which a child was found with paratyphoid, and several of the dairyman's staff afterwards became infected. In the Tenterden (Kent) outbreak there were some 60 cases, mostly between August 9th and Sept. 26th. The dairy was supplied by six farms, at one of which the farmer, his wife, and both the children were found to have had attacks of paratyphoid. The source of the illnesses of this family was thought to be the polluted well of the farm. Fortunately there were no fatal cases either in Hertfordshire or Kent, though some of the patients were seriously ill with all the classical symptoms of enteric fever, except hæmorrhage and perforation. Owing to the long incubation period and insidious onset of the enteric fevers, most of the damage may be done before the milk-borne outbreak is discovered, although the number of cases may be restricted by stoppage or pasteurisation of the milk, hospitalisation of patients, and inoculation of contacts.

Prevention consists in securing safe water-supplies for all dairy farms, and the handling of milk by persons in good health and of scrupulously clean habits. Dr. W. G. SAVAGE has recently shown how inefficiently the available water-supply of a county is sometimes distributed amongst the local authorities. But however well the water-supply is pooled, there will always be outlying farms faced with a difficulty in getting the large quantity needed for a dairy. Again, year by year Colonel HERBERT JONES, for long medical officer of health for the Herefordshire combined district, has pointed out in his annual reports how apathetic district councils and occupiers are in securing the protection of dip wells, surface wells, and springs, and how easily this protection may usually be afforded. The problem may be narrowed down to the keeping of all human excreta from the water-supply, and to the prevention of specifically infected excreta reaching milk and food by way of the fingers or clothes of those whose business it is to handle milk and food. As regards the purity of water, too much reliance is placed on occasional analyses, chemical or bacterial; what ought to be known is the history and circumstances of the water, and if a well is insufficiently protected from surface pollution it should be condemned on sight, in spite of any analysis. As an example of the unreliability of analysis alone it may be noted that the water of Watermill Farm, which was thought to be the origin of the Tenterden outbreak, was reported in May to be of "fair organic quality only," whereas in August, during the outbreak, it was "highly polluted" and "quite unsuitable for drinking purposes." As regards those employed at dairies, it is probably impossible to exclude from work all who have slight ailments. The farmer at Watermill was said to have been indisposed for two weeks, but for all that period except two days he had milked the cows and carried on. Dr. HYSLOP THOMSON writes that quite a number of carriers in the West Hertfordshire outbreak gave very vague histories of illness, and that one or two said quite definitely that they had never been ill at all. Obviously we have no knowledge to enable us to exclude such ambulant patients or carriers from handling milk or foodstuffs, and we must therefore attempt to secure scrupulous personal cleanliness on the part of all food handlers. It has been well said that the Hindu custom of washing the anus after defæcation is an excellent one. With Western appliances it is easy to improvise an effective sponge for the purpose by holding the toilet paper in the clean flush water, and the use of such a sponge incidentally prevents irritation, pruritus, cracks, and other circum-anal trouble. It should always be followed, of course, by very careful washing of the hands, and it is much more important that children should be taught to

wash their hands after attending to the wants of nature than to wash them before meals, often as a mere matter of form. With cleanly habits, a dairy farm worker would cease to be a danger, even if he were a typhoid carrier.

Milk-borne epidemics of scarlet fever and other diseases, to which we made brief reference in our issue of Dec. 3rd (p. 1194), generally arise from missed cases, and the measure to be adopted against them is separation of the milk business from the life of the household with the exclusion of non-immune children from the dairy. Possibly preventive inoculation will soon become the rule for the family and workers on dairy farms, just as it is now the rule for the staff of isolation hospitals.

RADIUM TREATMENT OF CANCER.

SURGERY has been slow to admit radium into its armoury for combating the ravages of cancer, but year by year the evidence grows that radium is of real utility. It is our belief that this evidence will accumulate at an ever-increasing rate, and that it will not be many years before radium is recognised to be the best form of treatment for some forms of cancer, with the result that some operations now frequently practised will fall almost into disuse. The supply of radium available in this country has never been large, and those who have used it in a scientific manner have been few, but the result of their work is beginning to make itself felt. The Medical Research Council has now published its fifth report[1] on this subject, giving a summary of the work done at research centres during 1926. It is, perhaps, ungrateful to complain that the report has appeared almost a year after the period to which it refers, so that it is already by so much out of date. But if our predictions are true, and radium is to become a tried and trusted weapon instead of an experimental one, the interests of sufferers from cancer will be best served by a more prompt publication of evidence. The report is couched, as usual, in cold, considered terms, so that no distrust is aroused in our minds by enthusiasm or partizanship. We gain the impression that results are improving as experience grows, and the chief interest will be aroused by the reports from the research centres at St. Bartholomew's and the Middlesex Hospitals. Some of the results at St. Bartholomew's were described earlier in the year in the *Hospital Reports* for 1927. These have already been the subject of comment in our columns,[2] and we have drawn attention to the remarkable degree of success attained in treating carcinoma of the breast, cervix, larynx, and tongue. A private demonstration of patients treated by radium held recently at this hospital has further impressed us very favourably. The Medical Research Council's report points out that in time valuable evidence as to the results of different methods will be obtained. In treating carcinoma of the breast the Middlesex Hospital tends to use a large dose of radium for a short time, whereas at St. Bartholomew's a widely distributed smaller dose is used for a much longer time. Much can be said for the second method, as the cancer cell is believed to be more vulnerable at some stages of its life-history than at others, and the longer time will cover more of these stages than the shorter. The report also gives interesting details of the method used at St. Bartholomew's for treating intrinsic carcinoma of the larynx. By means of windows cut in the thyroid cartilage, the radium is placed in close proximity to the growth and is allowed to remain there for several days, with very satisfactory results. That part of the Council's report which deals with the treatment of carcinoma of the cervix is reinforced by the article by Dr. HELEN CHAMBERS printed in our present issue. Dr. CHAMBERS claims that upon the evidence now available "it has been conclusively proved that for the large majority of patients suffering from cancer of the cervix modern radium treatment can completely replace surgery and give equally good and long-standing results." This claim is likely to give rise to some discussion. If it can be upheld, and the patients concerned are consulted as to which form of treatment they would prefer, radium or operation, there can be little doubt of their answers. Dr. CHAMBERS admits that a serious objection to radium therapy remains—namely, its failure to treat pelvic lymphatic glands. A similar difficulty, in the mediastinal glands, confronts those who would treat carcinoma of the breast. Even with carcinoma of the tongue and larynx where the lymphatic glands, being in the neck, are accessible, they have not proved easily amenable to radium. Operation, however, is confronted with the same limitations, and radium treatment need only give results as good as surgery to be preferred by both doctor and patient. We await further developments with the greatest interest.

[1] Special Report Series. No. 116. H.M. Stationery Office. 1927. Pp. 24. 1s.

Annotations.

"Ne quid nimis."

THE SCRIVENER.

A CORRESPONDENT voices the old but evergreen complaint of his time being so much occupied by filling in forms and writing certificates as to interfere with the treatment of his patients. It seems to us that much of his complaint is legitimate and that he describes a situation which is becoming ever more serious. It cannot really be in the public interest for the practitioner's time to be occupied to such an extent with describing what he has done, as to leave little time to do anything to describe. No doubt there is a substantial residue of clerical work inseparable from general practice. The keeping of records and the furnishing of certificates is part of the contract made by every insurance practitioner with the Commissioners, as also is the filling up of reports on insured persons suffering from tuberculosis. Such reports are required for the proper administration of insurance benefits. On the other hand, much of the demand on practitioners for reports and certificates has no real bearing upon the proper treatment of the case and as such is an unreasonable demand unless the patient is prepared to pay for the extra time involved. This sort of clerical work is essentially different from the keeping of records and the taking of clinical notes. The existence of a record of previous history and treatment facilitates the subsequent conduct of a case and curtails the time required for later consultations. Reports on cases sent to hospital and under dispensary supervision for tuberculosis are of importance alike to patient and practitioner. They imply, it is true, a tacit recognition that the practitioner has become a servant of the public, as well as the servant of his patients; but this can hardly be considered any longer in doubt. With regard to the clerical work of insurance practice two alternatives present themselves. Limiting the size of the panel would proportionately reduce the clerical work involved; to some extent no doubt the quality of panel work is in inverse ratio to the quantity, but a practitioner cannot afford to limit the number of his patients unless he can be assured of an adequate fee

for each case, and limitation of lists would have to be accompanied by a corresponding increase in the capitation fee. But the practitioner, and still more the group of practitioners, with large panel list, can afford to train clerks to take unnecessary writing off their hands. Clerical assistance for the school medical service is recognised as a matter of course, and the time is no doubt coming when clerical assistance in practice will become something of a profession in itself.

MEASUREMENT OF MENTAL CAPACITY.

IN any branch of science it is desirable, from time to time, to look back and to survey the advances so far achieved, and in the light of that survey and with some realisation of what is still lacking to anticipate the lines of future research. This is what Dr. Cyril Burt has done for psychology in the space of a short lecture entitled "The Measurement of Mental Capacities," delivered under the auspices of the Henderson Trust, founded nearly a century ago to promote phrenological science. Psychology goes back to Greece, but up to very recent times it was a purely abstract science, a discussion of mind in general, an introspective study, and singularly unpractical. The work of the early phrenologists—Gall, Spurzheim, and the Combes—may be regarded as an attempt to reach some practical method of mental measurement, but relied too largely upon physical traits as indices of mental. Modern psychology, by becoming experimental and statistical and studying mind in the concrete, making its proper study "not man but men," has, as Dr. Burt shows, made possible a much more accurate estimate of the mental differences of individuals. He presents a schema distinguishing intellectual from temperamental qualities, and among both of these, inborn from acquired, and general from specific capacities. So far progress has been mainly on the intellectual side, tests of general intelligence and of specific educational acquirements having reached some degree of reliability, though not finality. Recent research has largely dealt with the question of special inborn capacities, such as those of sense-perception, manual capacity, linguistic ability, retentive capacity; psychologists do not yet agree regarding the relative predominance of "general" and "specific" abilities, but Dr. Burt shows the possibility even now of a comparatively reliable examination scheme based on a good working hypothesis. Tests for the study of temperamental qualities are not yet, however, available, and reliance must still be placed on the method of skilled observation. In spite of imperfections, however, work of much practical value for education and industry has been achieved, and some new light thrown upon the problems of lunacy and mental deficiency, not to say of human nature in general. The medical practitioner has always been necessarily a psychologist, but he need no longer be a mere empiricist.

CARBON MONOXIDE IN BATHROOMS.

RECENT work[1] by J. B. S. Haldane on the effect of atmospheres containing various proportions of oxygen and carbon monoxide shows that the movements of the wax moth and the germination of cress seed are inhibited by carbon monoxide, which has some positive action over and above mere dilution of oxygen. By taking advantage of the fact that mammals can live on oxygen dissolved in their blood under high pressure even when almost all their hæmoglobin is combined with carbon monoxide (as was shown by Haldane in 1895) he has observed that with rats an excess of carbon monoxide quickly caused hyperpnœa and convulsions. This result could usually be countered and the animal's life preserved by the addition of oxygen and a lowering of the pressure. It is, Haldane considers, clear that carbon monoxide has a poisonous action on rats, apart from its combination with hæmoglobin. This action he associates with a CO-sensitive substance in the brain as well as in the muscles, as shown by Keilin. A specific toxic action on the brain may account for the curious disinclination to use obvious and easy means of escape which persons who have recovered from carbon monoxide poisoning almost invariably recall. This tendency adds a peculiar danger to any source of carbon monoxide in a place where a person is likely to be left alone and undisturbed for some time. The danger has been so repeatedly emphasised in coroners' courts that we would have thought it was now common knowledge. Inquests held in various parts of London within the last few weeks have shown that gas appliances of bad design or almost perfect ones used under unfavourable conditions, have been responsible for deaths by carbon monoxide poisoning. Ordinary coal-gas or carburetted water-gas mixture, when supplied through a sound system of service pipes to appliances which can be trusted in all circumstances to burn it completely is one of the safest and most convenient sources of heat. The vile and insistent smell of carburetted water-gas is an effective set-off to its high content of carbon monoxide. The real danger is the appliance in which the burning, or rather attempted burning, of any gaseous mixture containing carbon may lead to imperfect oxidation and formation of carbon monoxide. This danger, potentially ever present in such highly efficient water heating devices as geysers, can apparently never be overcome with certainty even by arrangements intended to lead the products of combustion outside the building—an absolutely necessary precaution. The very small bathrooms now provided in flats certainly add to the danger. This could be much reduced if people using geysers and water heaters for hot baths would (1) open the window a little at the top and leave the door wide open while the water is heating, (2) undress in their bedrooms and on entering the bathroom turn out the gas before starting to bathe, and (3) hang up on the door a notice to say "occupied" rather than bolt the door.

ACUTE APPENDICITIS IN PREGNANCY.

Dr. R. A. Wilson, of Brooklyn, has recently[1] reported ten cases of pregnancy complicated by appendicitis in women aged from 21 to 34, who had been treated in the obstetrical and surgical services of the Methodist Episcopal Hospital since 1915. With one exception in which the attack was primary, a previous history of appendicitis was obtainable in all. In eight cases pregnancy appeared to have an injurious effect upon the appendicitis, marked exacerbation of which took place. Three cases perforated and one died. Only one patient, however, miscarried, although three required drainage. About 80 per cent. of the cases of appendicitis complicating pregnancy occur in the first six months, the disease being comparatively rare in the last bimester. Dr. Wilson is of opinion that appendicitis is commoner in the puerperium than is generally supposed, but that it is frequently overlooked at this time. The diagnosis of appendicitis becomes increasingly difficult after the first months of pregnancy, especially if uterine contractions are present. The leucocyte count is not of much assistance owing to the leucocytosis normally existing during pregnancy. The maternal prognosis is good if an early operation is performed, but perforation is followed by a mortality-rate of 50 per cent. In simple cases there is little risk of abortion, but if perforation occurs abortion takes place in about 50 per cent. The more advanced the pregnancy the greater the risks to mother and child. Apart from a greatly increased incidence of pelvic phlebitis, complications are not more varied or more serious than those found after other cases of appendicitis. Treatment will depend on the extent

[1] Surgery, Gynecology and Obstetrics, November, 1927.

to which the uterine wall is involved in the infective process. In the absence of peritonitis the appendix should be removed quickly and the uterus left undisturbed, but if perforation and peritonitis are present a choice must be made between a low section and a Porro operation. Dr. Wilson's personal experience should be read in the light of an analytical study of 405 operations for appendicitis associated with gestation, collected from English, French, and German literature sources by Dr. A. P. Heineck, of Chicago.[2] In 21 cases the pregnancy was ectopic and in 384 intra-uterine. The ages of the patients ranged from 15 to 46, and the maximal frequency of appendicitis which might occur at any age was during the second, third, and fourth months. 279 cases were acute and 91 chronic. In 35 cases, owing to the incompleteness of the reports, an exact classification could not be made. 373 patients recovered and 32 died, the commonest cause of death being diffuse peritonitis. In the 21 cases of ectopic pregnancy the products of conception and the appendix were removed at the same time. In 205 cases a living child was born, and in 11 no mention was made of the viability of the child. In 92 cases either abortion or miscarriage followed the operation. Premature labour almost always attended by death of the baby was recorded in 71 cases on the day of operation or from one day to four weeks later. Dr. Heineck has drawn up tables showing the importance of early operation from both the maternal and fœtal standpoint, and the various operative procedures and anæsthetics used. Most of the cases made an uneventful recovery.

BIRTH CONTROL CLINICS.

IN the annual report[3] for 1927 of the Walworth centre of the Society for the Provision of Birth Control Clinics is included a statistical summary of the activities of the various clinics affiliated to the Society. Of these clinics, there are now nine, situated at Walworth, North Kensington, Wolverhampton, Cambridge, Manchester and Salford, East London, Glasgow, Oxford, and Birmingham. Up till August 1st, 1927, there had been seen at these clinics a total of 13,022 "new cases" and 17,228 "return cases." The doctors working at these clinics are not bound to adhere to any one contraceptive method, but the technique which finds most favour for normal women is a combination of an occlusive principle, a spermicidal principle, and a douche. This is the technique most approved by a medical committee that has recently reported on the question.[4] The occlusive device most used is the "Dutch cap," which is made in 16 sizes, ranging from 45 to 90 mm. in diameter. A cap is adjusted of such a size that while held firmly in place it causes no discomfort to the wearer. The spermicide now favoured is an ointment containing 1 per cent. lactic acid, which the woman is instructed to apply to the rim of the pessary before adjusting it. She is further told to douche herself with warm water on getting up in the morning after the pessary has been used. The process of adjusting a pessary of suitable size is one which calls for experience on the part of the examining physician, who, by the rules of the Society, must be present at all sessions. The rule in question runs as follows: The objects of the Society shall be "in the interests of social welfare and for the relief of poverty, to establish and support clinics in which instruction in the most satisfactory method of contraception will be given to married women in poor circumstances by registered medical practitioners (preferably women) assisted when necessary by qualified nurses. The medical practitioners shall be solely responsible for the treatment of patients, and the nurses shall act only under the instructions of the medical practitioners." The phrase "in the interests of social welfare and for the relief of poverty" is important because it implies that the Society aims at serving a purpose which is socially as well as medically useful. Thus, conditions of economic stress arising, for instance, out of housing or financial difficulties are taken by the Society as a justification for giving to a woman advice on birth control. The issue was brought to a head when a majority of the committee of the Aberdeen centre decided that no woman could be accepted as a patient unless she brought a recommendation from a medical practitioner. Medical grounds were regarded by this committee as the only ones on which advice on birth control should be given. Hence the Aberdeen centre has been erased from the roll of centres affiliated to the Society. It is clear that the term "medical grounds" is capable of interpretation in a narrow and in a broad sense. In the narrow sense it would approximately be restricted to such conditions as cardiac, venereal, renal, or hereditary diseases, tuberculosis, and pelvic abnormalities. But in a broad sense the phrase might be interpreted as including considerations of health involved in the proper spacing of all children born, the danger of using ill-fitting occlusive appliances without medical supervision, and the harmfulness of the practice of coitus interruptus which is the method of birth control resorted to by the great majority of those to whom other and better methods are not known. That these clinics fulfil a useful medical purpose few persons acquainted with their work will deny.[5] That they also perform a useful social purpose is shown by the letters of gratitude and thanks (some of which are published in the Walworth report) which the Society constantly receives from women who have benefited from its activities. These clinics, which are maintained entirely by voluntary subscription, welcome visits from medical men or women interested in the work.

THE FAMILY DOCTOR AS SPECIALIST.

TO-DAY the knowledge required by a family doctor is growing with every advance in medicine to an extent which makes it increasingly difficult for one brain to grasp more than the rudiments of the many subjects required of it. The result of this is a growing tendency to specialism even by doctors in general practice. In the Alexander Black memorial lecture[6] Dr. Charles E. Douglas discussed the opportunities for the family doctor as a specialist on certain lines in his own sphere which do not encroach on specialised work outside of it, yet are of great service to the community. He began by tracing the rise of the family doctor to the eminent position which he held about the middle of the last century, a position reflected in the literature of the time by such characters as Lydgate in "Middlemarch" and in life by such men as Dr. Francis Adams and Dr. Charles Hastings. He then went on to discuss the reasons for the decline in usefulness and status of the family doctor since that time. This Dr. Douglas attributes to three factors: the rise of antiseptic surgery, which has made it a vast specialty in itself; the growing tendency to collectivism, of which the public health laboratory and the fever hospital are examples; and lastly, the most directly causative factor, the national health insurance scheme. From the point of view of the community—which is naturally and properly the most dominating point of view—this scheme is, he says, as near an unmixed blessing as it can be. But, he adds, "a cumbersome form of certificate with regulations to enforce it . . . is the bugbear on the one hand; and on the other is the presence of a 'checking bureau' which is on the alert to insist upon economy in prescribing . . ." These two influences with the resulting complaints, exactions, fines, and humiliating experiences before panel committees or even medical service committees

cannot fail, Dr. Douglas thinks, to have a demoralising effect upon the panel doctor, who is the family doctor of the working classes and to degrade him in the eyes of the general public. The family doctor can, however, regain his lost status by becoming a specialist in his own domain. Most research is difficult for him because he is more concerned with its practical results than with its scientific aspect, and if he attempts it, owing to lack of material of one kind, he is liable to argue from insufficient data. In spite of these difficulties he can do special work in regions where no one else but he has access. He may study the beginnings of disease. In country districts he should practise urgent surgery so that he can operate on a case of laryngeal diphtheria, acute appendicitis, or strangulated hernia. He may take part in collective investigations, as was done 40 years ago when the communicability of phthisis, pneumonia, and chorea were examined by 6400 doctors. He may assist in the prevention of disease by promoting regular medical examination in health. Finally, he may exercise the "scientific imagination." One man's experiences as a family doctor of a group of cases is usually too small for him to use the inductive method of research, but speculative reasoning has led to advances in the science of medicine. Harvey, Jenner, Sir James Mackenzie, and Lister all used the deductive method, and there is still room for it to-day. Dr. Douglas concludes by emphasising the part played by the family doctor as a friend and advisor on matters outside the realm of medicine, where he is the nearest approach to father confessor that we in this time may see. He it is also who is curator of the truth that medicine has a body of its own and is not a mere bundle of specialties.

HEADACHE CURED BY THECAL INSUFFLATION.

PATIENTS complaining of headache and dizziness as a sequel to accident have been rather unwelcome patrons of most clinics. They are often living in hopes of financial compensation, and this fact, together with the absence of abnormal physical signs, may lead to an unmerited diagnosis of traumatic (or compensation) neurosis. In an article in the current number of *Surgery, Gynecology and Obstetrics* Dr. Wilder Penfield, of the Presbyterian Hospital, New York, records some remarkable cures in such cases by the insufflation of air into the subarachnoid space; his results in seven instances have been so consistently good that he regards the treatment as specific for this condition. The patients to whom it has been applied had all suffered from injury to the head, five of them had been rendered unconscious at the time of their accidents and fracture of the skull had been demonstrated in three. Headache and dizziness were their cardinal symptoms. The site of the headache either corresponded with the site of the blow or was frontal; pain was invariably localised and in most cases was situated near the site of the blow, with some tendency to radiate forward. Usually it was a dull pain—three patients described it as hammering—ordinarily it was made worse by lifting, blowing the nose, or stooping, but such aggravation was not invariable. The headache in cases of this kind is usually present every day, but may have diurnal variations, coming on shortly after rising and again in the late afternoon; most patients are unfavourably influenced by stormy weather and some by a warm day. The vertigo occurs in transient attacks each of which lasts for several minutes, and is not accompanied by nystagmus or any sense of rotation. As a result of air insufflation all the patients treated have been relieved of their headaches completely, all were enabled to resume their normal acitivity by day and to sleep soundly by night. Their ages varied from 4 to 65 years, and the interval between injury and treatment from four weeks to eight years. Air was injected into the lumbar theca, 5 c.cm. of air after withdrawal of each 5 c.cm. of cerebro-spinal fluid, while the patient lay on a tilted operating table in such a position that the highest portion of the head corresponded with the site of the headache. In such a position the air passes up over the convexity of the brain, and very little of it enters the ventricles. A total of 42 to 95 c.cm. of air was reached, a quantity sufficient completely to fill the cerebral arachnoid spaces and basal cisterns. After the injection the side of the head where the pain was habitually most severe was kept uppermost, and the top of the bed slightly raised by blocks. The immediate reactionary headache lasted from three to nine days, and with the absorption of the air the headache disappeared and did not return. Instructive radiograms of these cases are published with the paper. In some cases the "pneumographs" gave evidence of atrophy of the frontal convolutions; in three, air had escaped from the subarachnoid into the subdural space; in two a definite subarachnoid cyst was seen. The fact that a certain group of headache cases is apparently curable by a specific form of treatment makes it likely that they are caused by a common mechanism, and this mechanism, in Dr. Penfield's opinion, is some abnormality in the cerebral meninges.

THE PSYCHOLOGY OF ANTIVACCINATION.

UNDER the title "Should we be Vaccinated?" Mr. Bernhard J. Stern, instructor of sociology at Columbia University, has written a history of vaccination and the controversy concerning its efficacy and dangers.[1] He has a firm belief in its value and discusses why the controversy still exists 129 years after the appearance of Jenner's *Inquiry*. Within a year of this publication both advocacy and denunciation had become equally and extremely intemperate, each side accusing the other of being influenced by financial interests. By 1804 both parties were so far from an unprejudiced desire for truth that the title-page of Dr. Rowley's brochure, among 12 lines of abusive language, offered treatment for the beastly new diseases produced from cow-pox, whilst the Royal Jennerian Society angrily refused to institute experiments to determine whether there was a period to the preservative powers of vaccination. The chief motive attributed to the early opposition—a vested interest in inoculation—has long ceased to be operative, but it is probable that the virulence of the strife has left us a legacy, for we still meet the belief, freely inculcated in those days, that vaccination is a gigantic fraud deliberately perpetuated for the sake of gain. The estimation of the value, limitations, and possible dangers of vaccination against small-pox is now a commonplace of scientific medicine, and the field of preventive vaccination is so widened that what in Jenner's time was an isolated empirical observation now takes its place among a group of prophylactic measures. The opposition to vaccination, however, still retains the "all or none" quality of primitive behaviour and, like many emotional reactions, is supported by a wealth of argument which the person reacting honestly believes to be the logical foundation of his behaviour. An antivaccinator is generally an antivivisector, often a vegetarian, but he is ready to base his objection to vaccination upon arguments, statistical or individual, that have no relation to his other negativisms and are therefore not the true foundation upon which his objection rests. In this common tendency to produce reasons for beliefs already formed upon an emotional basis we find the explanation for the failure to settle some controversies by appeal to facts. If a belief depends upon an emotional state we can by arguments only convince a man against his will, and the proverb tells us what happens next. The granting of validity to a conscientious objection to vaccination has the advantage of meeting the objector upon his own ground; moreover, since emotion is directed against persons rather than against things—in this case, perhaps, against person-

[1] London and New York: Harpers, 1927: Pp. 146.

ifications of authority, medical or legislative—the emotion is allowed a chance of subsiding. The risk of allowing a part of the population to escape protection from small-pox may not be too great a price to pay if the result is to bring the vaccination controversy into that world of cold reason where two and two make four.

THE RED BLOOD CELLS IN MALARIA.

CHANGES in the red blood corpuscles, caused by the malarial parasites developing in them, are thought to be of practical importance because some of them are peculiar to particular kinds of plasmodium and differentiate the three morphological types of parasite. The common changes seen in malaria include enlargement and decolorisation, shrinkage, the "old gold" or brassy globules of Marchiafava and Celli, fragmentation, and agglutination. In 1899, however, Schüffner described the speckling which bears his name in the red cells invaded by the benign tertian parasites, and shortly afterwards Stephens and Christophers and later Maurer demonstrated in the cells attacked by the subtertian parasite special dots of a new kind and useful in differentiating the various kinds of parasite. Opinions about the specificity of Schüffner's dots are not entirely in agreement, but most observers think that they represent a characteristic and differential element. Stephens and Christophers believe that Maurer's dots are characteristic of subtertian malaria, and Maurer himself holds them to be a decisive phenomenon which differentiates the parasite "*Laverania malariæ*" and justifies a certain diagnosis. Recently Prof. Salvatore Pastore,[1] of the University of Rome, has endeavoured to settle the controversy as far as possible and has examined blood-films stained by the methods of Giemsa, Romanowsky, and Brug. He found Schüffner's dots in all stages of the development of *Plasmodium vivax*, but the corpuscles harbouring parasites which occupied only one-fourth of the cell showed them less often than corpuscles inhabited by growing forms and by adult schizonts. In very young parasites which occupied less than a quarter of the corpuscle the speckling was absent, although the cell was enlarged; in adult forms the dots were not only more numerous, but of a larger size. With *P. præcox* infections red corpuscles were found having dots which did not resemble in form the very fine ones of Schüffner. Maurer's dots were seen in corpuscles invaded by *P. præcox*, but more often in the larger ring forms than in the smaller, and also with greater clearness. From these observations the following doctrinal and practical conclusions may, perhaps, be drawn. The genesis and significance of Schüffner's dots and Maurer's dots are obscure; our very limited knowledge of the intimate structure of the red cell prevents us from explaining them fully. They appear in corpuscles whose parasites are not mature, and increase in numbers with the parasite's growth. Schüffner's dots are found most frequently in red cells infected with *P. vivax* and have therefore been regarded as characteristic of this parasite. Though Prof. Pastore has seen them occasionally in red cells occupied by the parasite of quartan in the sporulation phase they are nevertheless useful to differentiate in doubtful cases between the ring forms of parasites of the *vivax* type and those of the *præcox* type, and it is certainly exceptional to find red dots in cells infected with *P. præcox*. When such dots do occur they have different characteristics from those of Schüffner. Maurer's dots, which are variable in shape, size, distribution, and rarely exceed 7–8 in number, have been held to be specific of the corpuscles infected with *P. præcox*. Later investigators have shown, however, that they are not exclusive to *P. præcox*, being found also in cells infected with *vivax* and even with the quartan parasite. These observations are confirmed by Prof. Pastore, who states that Schüffner's dots, by their frequency and ease of demonstration, are of much more interest than Maurer's. They may be seen both in the asexual and sexual forms of *P. vivax* and hence their appearance does not completely differentiate between the gametic and the asexual cycle. In *præcox*, however, every trace of speckling in the gametic cycle is wanting.

INFLUENZA.

EACH winter there comes a series of weeks during which the mortality from all causes and especially from the respiratory group of diseases is much higher than throughout the rest of the year. This high mortality is balanced by a low summer death-rate which reaches its minimum in June and July. The winter rise of the curve varies in its date of commencement, sometimes coming as early as November, at other times delayed into the new year. Not infrequently the curve has two peaks, one in the early winter and the other in spring, and in that event it often happens that a small amplitude of one of these excursions is compensated by the large amplitude of the other. In any case, certain features of this excessive mortality are practically constant—namely, the large part which respiratory disease plays in its production, the extent to which it falls on the extremes of life, more particularly on old age, and the coincident prevalence of colds in the communitv. There appears to be a close relationship between its occurrence and a combination of low temperature with high relative humidity, in other words, the meteorological conditions often associated with fog, a fact which ought to be taken into account when a heavy respiratory mortality is attributed to atmospheric pollution in smoky towns during periods of fog. From time to time the onset of these spells of heavy mortality is more than usually dramatic and is associated with an exceptional prevalence of a form of illness mainly involving the respiratory tract, but heralded by a definite prodromal period of prostration, which we call influenza. Apart from its epidemiological behaviour it is often difficult to differentiate this disease fron the severer forms of the "common cold." Its seasonal prevalence coincides with the annual increase of respiratory disease and mortality, and it affects the same age-groups of the population. Broadly, its recognition depends on the suddenness of its appearance and the quickness of its passage, while its occurrence may be retrospectively inferred from the high proportion of all deaths which have been attributed in any year to respiratory causes. In towns this proportion is normally well under 20 per cent., in influenza years it is always above that figure and usually approaches 30 per cent.

In 1918–19, however, influenza behaved in quite an unusual fashion. First of all, it made its first appearance in the summer, affecting a large number of people with sudden prostration, its extent being measurable by its striking influence on school attendance records and a perceptible and most unusual, if slight, rise in the mortality at that season. Later, in September, the really massive wave of prevalence commenced, that is, at a time of year much earlier than the usual onset of respiratory catarrhs. The circumstances of this outbreak and its recrudescence in the following February are still fresh in the memory of the peoples of the world, but it may be well to emphasise, in addition to its unusual seasonal incidence and virulence of attack, a notable involvement of the population at the prime of life. Consequently, this epidemic has been regarded as unique, and has been the subject of a vast deal of scientific inquiry. Its epidemiological and preventive aspects are dealt with at considerable length in three articles by Dr. E. O. Jordan, of Chicago, which recently appeared in the *Journal* of the American Medical Association,[1] and are to be published in book form with the help of a grant from the Committee on Medical Research. Dr. Jordan states, as the result of his own investigations and an extensive study of American and other literature, the arguments for and against the various measures which have been advocated for controlling

[1] Jour. Amer. Med. Assoc., Nov. 5th, 12th, and 19th, 1927.

such epidemics—e.g., isolation and quarantine, closure of schools and prohibition of public gatherings, face masks, preventive influence of certain gases, prophylactic inoculation, and general measures of hygiene and sanitation. His discussion is exceptionally well documented, but the conclusions are for the most part indefinite. It is obvious, of course, that complete isolation of a community, for a period of about three months from a date before infection could possibly have gained entry, would prevail against influenza as against any other infection which is conveyed directly from person to person. But such a procedure is impracticable for any but small groups of people already so isolated that they are unlikely to have the information which would guide them to take such anticipatory measures.

Dr. Jordan is probably right in surmising that early isolation of cases, and the employment of such precautions as the people themselves will exercise in a time of exceptional alarm, may slow down the rate of transmission and so limit the number of victims while the epidemic undergoes its natural process of elimination. For this purpose, pamphlets or advertisements issued by central or local health departments, conveying advice to the public, may serve a purpose, but the American specimens of such pamphlets here reproduced err, like our own, on the side of urging the impossible. These should restrict themselves to telling the patients to take to bed on the slightest suspicion of symptoms and call in the family doctor, while advising others to reduce their contacts to the minimum, by keeping as much in the open air as possible and by ventilating freely all rooms which it is necessary for them to share with others; for that advice sums up practically all our knowledge of the prevention of influenza. It must be confessed that in the present state of our knowledge we are practically helpless in the face of such a visitation as occurred in 1918–19, and that, if influenza were to assume the virulence of pneumonic plague—a similarly conveyed disease—nothing but the most rigid forms of domestic isolation accompanied by complete disorganisation of the life of the community could avail to prevent devastation comparable to that which has visited Manchuria in recent years.

NOT "MALTA" FEVER.

THE old catch, how to make the Maltese cross, has a modern instance in the very reasonable resentment of the island of Malta against having its name associated with the disabling fever which infests the whole of the Mediterranean littoral and from there has become far more widely distributed. Malta can claim association rather with the ætiology and prevention of the disease, for it was here that the work of Sir David Bruce was begun which proved it to be a separate pathological entity by the discovery of a micrococcus in the spleen. It was, however, Bruce who attached to this organism the specific name *melitensis*, a term which is unlikely to attract attention to Malta except on the part of those familiar with St. Paul's adventures on the island of "Melita." And the designation may be altered to *brucei* at the International Botanical Congress to be held in 1930, when nomenclature will come up for consideration. The annoyance, and even material loss to the island, caused by the unfortunate use of the term "Malta fever" is set out in a memorandum[1] recently presented to the British Medical Association by its Malta branch in association with the Camera Medica of Malta. The alternative name, "undulant fever," proposed in 1897 by Captain M. L. Hughes, R.A.M.C., and recommended by the International Congress of Medicine held in London in 1913, is now generally adopted by English writers, particularly when describing cases of similar fever due to Bang's bacillus. In our own official nomenclature "undulant fever" is given as the sole synonym of "Mediterranean fever," Malta not even being mentioned, while in the international list of causes of death the rubric Mediterranean fever contains the two subtitles, Malta fever and undulant fever. The official German designation of the disease is now *Mittelmeer-fieber*, while in the most recent French text-book on hygiene,[2] the chapter headed *Fièvre ondulante* includes a footnote relating that in 1910, at the request of the Governor of Malta, the English Government asked that the term "Malta fever" should no longer be employed in official French documents. In 1911 the Académie de Médecine agreed to the use of *mélitococcie*, two years later replaced by *fièvre ondulante*. French nosology, however, continued to employ indifferently the expressions *fièvre de Malte*, *fièvre méditerranéenne*, and *mélitococcie*. Finally, the French Minister of Hygiene agreed to the denomination *fièvre ondulante* which now figures alone on the list for compulsory notification. With the disappearance of the word Malta from the official name of the disease, we shall lose almost the last survival of topographical names for disease. At one time very widely employed, the term "German measles" alone has survived, and should it cause any qualms in Teutonic medical circles we would repeat our willingness to exchange it for the surrender of the term *englische Krankheit* for rickets, which may seem to some to carry a slur—possibly indeed not altogether unmerited.

[1] See Brit. Med. Jour., Dec. 17th, p. 1158.

THE GREAT SLIDE OF DEC. 21ST.

WEDNESDAY in last week will long be remembered in the annals of the London hospitals. By a climatic freak, which is, happily, exceedingly unusual in this country, a fall of rain on frozen ground during the previous night glazed the roads and footpaths with a sheet of ice. Such conditions are much more perilous than those created by frozen snow, the inequalities of which afford some kind of foothold. Night workers returning home and those who started out to their employment long before daylight, with no suspicion of what had happened, as well as those who left much later, found walking an enterprise of great danger, while for horses and motor vehicles movement was possible only at the risk of disaster. The inevitable trouble began immediately. Road traffic was at a standstill and pedestrians, despite the aid of walking-sticks and the help given by clinging to railings, where such were available, lost their footing and fell in thousands. Most of them were fortunate enough to escape with shakings and bruises, but in a large number of instances injuries were serious enough to require surgical assistance, and by shortly after 5 o'clock in the morning ambulances and hospitals were busy, while as time went on the demands upon both were overwhelming. The pressure at some of the great hospitals was so severe that there was not time to keep accurate records, but it would appear that the ten or a dozen principal hospitals treated over 2000 cases in a few hours. Between 9 and 10 o'clock the glazed surface began to soften, and the stream of casualties gradually dwindled, but not before doctors, nurses, and ambulance drivers had reached the limits of endurance.

It is the experience of all large hospitals that the first fall of snow will bring in several cases of Pott's fracture and dislocated shoulder, chiefly due to slipping off the edge of the pavement, but the experience of Dec. 21st stands alone. Simple cases were by no means rare on that occasion, but many were more serious, though the number of really grave fractures was comparatively small. The crowded industrial district around Guy's Hospital appears to have suffered more severely than any other, and we gather that some 300 casualties were treated there during the day, about a score of which were serious. St. Bartholomew's, St. Thomas's, King's College, the West London, and the Royal Northern Hospitals each treated 200 or more cases. The London and St. George's Hospitals got off more lightly,

[2] Course d'Hygiène. Edited by Léon Bernard and Robert Debré. Masson et Cie. 1927.

though in each case the expression is purely relative. The proportion of broken limbs is not readily ascertainable, but, taken all round, it would appear to have been, roughly, about 10 per cent. The total number of patients detained was, of course, small. Many fractures do not require detention, and in some of the hospitals there were few or no available beds, as at Queen Mary's Hospital at Stratford, where the half dozen fractures, out of a total of 158 casualties, had to be sent to other institutions. At the London, St. George's, and West London Hospitals there were only six or eight detentions each—no doubt there would have been more had there been a larger number of vacant beds. This trying experience was not confined to London. It is reported that in Birmingham, the largest provincial town in England, more than 100 casualties were dealt with, while in many parts of the country the roads were encumbered with stranded motor vehicles. Happily a thaw ended the trouble in a few hours, though it is to be feared that many weeks will elapse before the last sufferer is cured.

That the emergency was met so rapidly and successfully is a definite tribute to the efficiency of the London hospital and ambulance services. The smaller institutions in town and suburbs were, proportionately, as hardly pressed as those which can rapidly mobilise very large resources, and although the ambulance service has often been criticised, it would appear to have emerged from the trial admirably enough, though delays, when calls were incessant and the highways highly dangerous, were inevitable. To the voluntary hospitals no more crucial test could have been applied, and the manner in which they met it is the best indication of the manner in which their resources can be expanded to meet a pressure so acute as to be without precedent.

Prof. J. K. Jamieson, Dean of the Faculty of Medicine of the University of Leeds, has been nominated representative of the University on the General Medical Council.

AT the Royal Society of Medicine's reception to be held at 1, Wimpole-street on Monday, Jan. 16th, Dr. Jane Walker will give an address on Sanity, Medicine, and Surgery. The Wellcome Historical Medical Museum is lending a large number of exhibits, and Dr. Walker has collected many paintings illustrating her subject. Guests will be received as usual from 8.30 to 9 P.M., but the address will be given at 9.15 instead of 9.30. Tickets of admission will be required by those who are unaccompanied by a Fellow of the Society.

DONATIONS AND BEQUESTS.—The Corporation of the City of London has allocated, under the bequest of the late Mr. A. B. Bosher, the following sums of money to hospitals: Guy's, London, and St. Thomas's Hospitals, £6000 each; Middlesex, £5000; St. Mary's, £4000; St. Bartholomew's, Royal National Orthopædic, Royal Northern group, St. George's, University College, and the West London, £3000 each; Charing Cross, King's College, Metropolitan, Royal Free, and Westminster, £2000 each; City of London (Victoria Park), East London, Hampstead General, London Fever, London Temperance, and Queen's, £1000 each; Belgrave, East End Mothers', Elizabeth Garrett Anderson, London Lock, Miller, Mothers', Queen Charlotte's, and St. Paul's, £500 each; Central London and Chelsea, £400 each; St. John and St. Elizabeth, St. John's (Lewisham), and South-Eastern, £300 each; Mildmay Mission, St. Peter's, British (for Mothers and Babies), Hospital for Epilepsy, Kensington and Fulham, North Islington, Paddington Green, Samaritan, and West End Hospitals, £200 each; St. John's Hospital for the Skin, Streatham Babies' Hospital, and Central London Ophthalmic, £100 each. Under the same bequest the Sheffield Corporation has divided £27,000 among Sheffield hospitals—namely: Sheffield Royal Infirmary, 45 per cent.; Sheffield Royal Hospital, 43 per cent.; Jessop Hospital, 8½ per cent.; Children's Hospital, 3½ per cent.—Mr. Albert Levy, hon. treasurer of the Royal Free Hospital, has added £14,000 as a Christmas gift to the £6000 he has already contributed to the hospital's funds. The President, Lord Riddell, has increased his donation by a similar contribution.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLVI.

THE TREATMENT OF EMERGENCIES IN ANÆSTHESIA.

THERE may come a time to all anæsthetists when the death of the patient appears imminent. The unavoidable occasions are those in which an operation is performed as being the only means of saving a patient's life, but entails bad risks both for the surgeon and for the anæsthetist. In the avoidable cases, which diminish as skill in anæsthesia increases, there has usually been a failure on the part of the anæsthetist to observe, or to interpret, such untoward signs as may have been present. For the successful treatment of such cases it is of supreme importance that the anæsthetist should not wait until the patient is in extremis. The futile administration of oxygen or CO_2 after the stoppage of respiration, or the injection of potent drugs under the skin when the heart has ceased to beat, is still seen too frequently.

Emergencies fall naturally into two groups: (*a*) partial or complete stoppage of respiration; (*b*) failure of the circulation. The failure of either of these systems may be nervous in origin, and if one fails the other will do so unless remedial measures are taken speedily, and are successful.

Respiratory Difficulties.

The causes of respiratory difficulties may be classified, according to their manner of affecting the respiration, as (1) obstruction of the air-passages; (2) interference with the respiratory movements, and (3) interference with the nervous control of respiration.

Obstruction of the air-passages.—In the first division are included such conditions as spasm of the upper respiratory tract; the presence of foreign bodies such as teeth, tonsils, or blood-clot in the larynx or trachea; the presence of fluids such as blood, pus, mucus, or vomit in the trachea; swelling of the mucosa, as in œdema of the glottis; and alteration in the normal anatomy of the tract as in the collapse of the trachea in goitre, or the falling back of a wash-leather epiglottis. Treatment must aim at relieving the obstruction without delay. In a condition of spasm the obstruction usually occurs in the early stages of anæsthesia, and is due to the administration of a greater concentration of anæsthetic than will be tolerated by the patient. Temporary cessation of the anæsthetic and a few breaths of air or oxygen will usually relieve this. If necessary, the mouth must be forced open and the tongue held forward. If a foreign body descends to the larynx, the patient's head must be lowered at once and an effort made to remove it. This is a type of accident that occurs not infrequently in children's clinics for the removal of tonsils and adenoids. Blood-clot, tonsils, or loose temporary teeth may drop down the throat and become a source of danger. The child should at once be held up by the legs while a careful search is made for the foreign body. If impaction in the larynx takes place, a tracheotomy may have to be performed. For fluids in the throat the same treatment must be adopted. To lower the head is the best means of removing the fluid. The passage of a stomach-tube during induction in cases of acute intestinal obstruction will often prevent the inhalation of large quantities of fæcal vomit. Where there is the possibility of hæmorrhage, as in buccal operations, the anæsthetic should be given by means of a nasal catheter, the pharynx being well packed with gauze or sponge. In cases of retropharyngeal abscess, where there may be a sudden burst of pus into the throat, if a general anæsthetic is required it should be given either by the intratracheal method or through a laryngotomy tube. The anæsthetist must be pre-

ared to lower the head rapidly should the abscess urst during induction. With an œdematous larynx, s in Ludwig's angina, a tracheotomy may be a ecessity. In the removal of large goitres a softened achea may collapse suddenly and obstruct the spiration. Intratracheal anæsthetic should always e given in such cases to avoid trouble in the middle the operation. Lastly, it sometimes happens that hen full anæsthesia is reached the epiglottis may ll backwards and cover the top of the larynx. If is so-called "wash-leather" epiglottis be hooked wards, respiration will proceed normally, and for ie continuation of the anæsthetic a tracheal catheter ould be passed.

Interference with the respiratory movements may be ie to the pressure of instruments on the patient's igastrium; to the pressure of the viscera on the aphragm in a high Trendelenburg position; or to essure on one side of the thorax if the opposite lung out of action. Operators are liable to forget that though the abdomen makes an excellent instrument ble it was not intended to serve as such. Two or ree pounds of cold steel placed on the epigastrium an already shocked patient or a child may cause arked dyspnœa. With very obese patients, especily if chronic cardiac or pulmonary disease is esent, a high Trendelenburg position sometimes oduces cyanosis and dyspnœa. To these patients ygen must be given, and they should only be kept ted for as short a time as possible. Patients who ve only one functioning lung may require operation the diseased side of the chest. If lying on the und side causes embarrassment, the shoulder ould be supported with a pillow so as to enable e chest wall to expand freely.

Interference with nervous control of respiration may brought about by (1) toxæmia, from overdose of æsthetic; (2) anæmia, from excessive fall in the ood pressure; or (3) reflex inhibition, as when erative measures are started on a partially anæsthed patient. The treatment is the same for all cases. ie anæsthetic must be discontinued and the patient's ad lowered. Oxygen and CO_2 (5 per cent.) should be ministered by inhalation, and if respirations have ased they must be continued artificially. A powerful mulus, such as the stretching of the anal sphincter, ll often start respirations again. Two drugs are rticularly useful here, and both should be injected. ychnine gr. 1/30 is valuable for its action on the tor cells of the spinal cord, and lobeline gr. 1/10 a powerful stimulant to the respiratory centre. It s sometimes happened that premature lowering of head in cases where a spinal anæsthetic has been en has led to paralysis of the phrenic nerves. In h cases strychnine must be injected and artificial piration carried on until the effect of the drug has ased off.

Circulatory Difficulties.

Circulatory difficulties may be (1) due to the direct ct of the anæsthetic; (2) due to the effect of the ration; and (3) due to failure of respiration. nerally speaking, the anæsthetist is given warning the presence of a rapid and possibly irregular se, and by the presence of cyanosis.

Effect of the anæsthetic.—Where the anæsthetic is ectly responsible for cardiac failure, either myodial degeneration or a poorly compensated valvular on is usually present. Chloroform is the chief nder. It exerts a toxic action on the heart muscle, ich action is accentuated in the presence of cyanosis. longed administration of gas and oxygen in old feeble persons may also cause heart failure. Its ct has been described as similar to that which ld be produced if the patient were made to run ill. An overdose of anæsthetic is liable to produce diac inhibition and bulbar paralysis. The anæstic is also held responsible in deaths from status phaticus. In treating these cases of circulatory ure the head must be lowered so as to keep the in well supplied with blood, and an effort must made to eliminate the anæsthetic. For this pure oxygen with 5 per cent. CO_2 should be administered. If the heart has not actually stopped beating the anæsthetist should inject cardiac stimulants intramuscularly. Those most likely to be of value are strophanthin gr. 1/240, caffein sod. sal. gr. i.–iii., or ether 1 c.cm. if the patient has not been having this drug. If the heart has ceased to beat, 5 minims of adrenalin (1/1000) should be injected directly into the left ventricle. Failing this, and as a last resort, the heart should be massaged through the diaphragm. Sudden concentration of chloroform vapour in the early stages of induction may cause the heart to fail by vagal stimulation. An injection of atropine gr. 1/100 given before operation is the best means of preventing this catastrophe.

Effect of the operation.—Failure of circulation due to the operation is most often attributable either to shock or to hæmorrhage, or to an embolus; less frequently to the lowered blood pressure which follows the injection of a spinal anæsthetic. In cases of shock and hæmorrhage it is essential that the patient be supplied with warmth and fluid. A transfusion of blood is undoubtedly the best method of giving fluid, and, failing that, saline should be given intravenously or by the rectum. The patient should be returned to bed as speedily as possible and warmth supplied by hot blankets or a hot air cradle. The foot of the bed should be raised on blocks and an injection of morphine should be given. If collapse occurs as a result of diminished blood pressure following a spinal anæsthetic, the head should be lowered and 1 c.cm. of pituitary extract (10 international units) injected intramuscularly. Pulmonary embolism is, fortunately, rare during anæsthesia. Its occurrence is sudden, and is accompanied by cyanosis and immediate cardiac failure. The anæsthetist can do little but administer oxygen.

Effect of Respiratory Embarrassment.

Where the respiration is primarily at fault, it is obvious that if breathing has actually ceased it will only be a matter of time before the heart also ceases, unless effective measures are taken promptly. If the respiration is obstructed a strain will be thrown on the patient's heart because of the greater muscular effort required to breathe and the deficient oxygenation which is liable to occur. If partially obstructed respiration is present for any length of time it may lead to heart failure in feeble or fatty patients or in cases where the heart is already weakened by chronic valvular disease or by myocardial degeneration. To treat the heart one must treat the lungs, and the obstruction must be relieved by whatever method the occasion demands, whether it be the use of an airway, support to the chin, alteration of posture, or alteration in the method of giving the anæsthetic.

Conclusion.

Prevention is notoriously better than cure. If there is any one method better than another in the prevention of fatalities under anæsthesia it is in the maintenance of a perfectly free airway. If emergencies should occur, let the careful anæsthetist remember these two rules—(1) keep the head low; and (2) let the remedies be prompt. It is better to start treatment five minutes before the patient is dead than five minutes after.

J. K. HASLER, M.B., B.S. Lond.,
Anæsthetist to St. Mark's Hospital, the Metropolitan Hospital, the Dreadnought Hospital, and the Miller Hospital.

Corrigendum.—In the article by Dr. Eric Pritchard which appeared last week allusion was made (p. 1357) to one of the vitamins as water-soluble D. This should, of course, read water-soluble *B*.

INFIRMARY FITTED WITH WIRELESS.—The Salford Union Infirmary and the Old Peoples Homes and Nurses' Home have been fitted with 783 headphones and 29 loud speakers. The entire installation has cost about £1000, towards which Mr. Alfred Willett, of Broughton, contributed £750, the remainder being raised by public subscription, as guardians are not allowed to incur expenditure on such apparatus.

RADIUM TREATMENT OF CANCER OF THE CERVIX.

BY HELEN CHAMBERS, C.B.E., M.D. LOND.,
FULL-TIME INVESTIGATOR FOR THE MEDICAL RESEARCH COUNCIL.

THE recent report issued by the Ministry of Health [1] on the results of treatment of cancer of the uterus is a matter of serious concern to all who are responsible for the treatment of patients suffering from this disease. The report is a statistical inquiry based on an analysis of the existing literature prior to March, 1926. It deals with the results of treatment of not less than 80,000 cases of uterine cancer and compares the results obtained by surgery with those obtained by radiology. Cancer of the body of the uterus is considered separately from cancer of the cervix, because the problems associated with the disease at these two sites are widely different.

Radium treatment of cancer of the cervix has been in extensive use in foreign countries since 1913 and a vast literature has accumulated, dealing with over 5000 cases. During the period under review surgical technique has reached its limits, for the methods of operation have been standardised for many years. Radiological technique, on the other hand, has been largely in the experimental stage, and although great advances in technical methods have been made, the limits of these developments have not by any means been reached. The technical methods adopted in the radiological treatment of the cases under review have therefore on the whole been more elementary than those of surgery; but, nevertheless, the results of radium compare very favourably. When the general results of these two methods of treatment of operable cancer of the cervix are compared they are found to be closely alike; there is, however, an important factor weighing against the surgical method, the relatively high operation mortality of 17 per cent. Compared with this radium has an immediate mortality of less than 1 per cent. When only inoperable cases, which are completely hopeless from the point of view of the surgeon, are considered, roughly 12·6 per cent. can be saved, for prolonged periods at any rate, by radium. This figure is based on a five-year period.[1]

These conclusions are a summary of the evidence produced by many different clinics, and they therefore have the special value that they are not subject to the bias of any individual observer. When the evidence is examined in detail the results are, of course, found to vary widely with different clinicians; they also vary with different countries, for some have advanced in technical methods much more than others. These facts mean that we have to advise patients suffering from cancer of the cervix (except perhaps in the very few cases* where the disease has only reached its earliest stage), that if they obtain modern radium treatment their prospect of life will be as good as if they submit to operation, and the immediate risk of radium treatment is practically nil. Needless to say, no woman will submit to a severe surgical operation when she knows that this is true. But the soundness of this outlook clearly depends upon what is meant by modern radium treatment. We have no right to advise against competent surgery, even with its comparatively high death-rate, unless there is a reasonable prospect that the alternative radium treatment will be carried out with all the skill and knowledge that science now possesses. The experience of the last 12 years has conclusively shown that radium therapy is a specialised art which completely fails to save life unless the essential technical conditions for success are understood.

* There are no data yet available for cases such as these treated with radium.

It is an astonishing fact that in this country w are much less advanced in the treatment of uterin cancer than certain foreign countries. Radium ha only been used in England on scientific lines for th treatment of this disease since 1921, and in very fe clinics only. Comparatively few of our hospita carry out radium therapy at all for these case many possess no radium, and some which possess have not enough to treat uterine cancer effectivel This is a deplorable state of affairs which urgentl needs rectifying.

The use of radium for the treatment of cancer the cervix requires a skilled gynæcologist with a intimate knowledge of the disease and its patholog and of the physical and biological properties radium. Without this equipment it is impossible t treat the zone involved by the cancer with a effective dose of radiation. In this disease the use radium has passed the experimental stage, althoug it is still in the transition period of a new form treatment. The technique will doubtless be subje to great improvements as experience and knowledg increase. Certain known facts, however, large determine the results. The object of this paper is emphasise some of these essential points of techniqu

General Method of Treatment.

There is as yet no general agreement as to the be means of treating cancer of the cervix with radiu Many different methods are in use and they vary i the quantity of radium used, the dosage, and th method of distribution. When the earliest cases we treated very little was known about the range action of radium tubes and applicators or the biological effects. The methods of treatment we largely empirical, and all treatment other tha surgery was looked upon as a palliative measur The clinician using radium in the early days on treated cases which were completely hopeless fro the surgeon's point of view, and looked upon a po result as the inevitable and unavoidable consequen of the disease. The usual method was to insert single tube applicator into the cervical canal or again the growth for a varying time, often for 24 hou In the great majority of cases the extent of the growt was far wider than the range of action of the applicato and in practice this treatment did little more tha treat the surface of the disease. Temporary benefi nevertheless, often followed. The case was the watched until definite signs of extension were eviden and the same treatment was then given again son two or three months later. It was usual to repe the treatment as long as the patient was well enoug to attend the out-patient clinic, usually for six nine months, and occasionally for several yea It is sincerely to be hoped that this method of trea ment will never again be carried out in England there is complete proof that it invariably fails. It like cauterising the surface of a carcinoma a hoping for success.

In contrast with this treatment is the metho adopted when an attempt is made to cure the diseas The range of action of the radium tubes and applicato and the approximate dose required to produce lethal effect on cancer cells are known within limit The treatment is planned soon after the patient first seen and the whole course of radiation carri out within a few weeks. The radiation is arrange so that an effective dose reaches as widely as possib in the region involved by the disease. If the growt recurs the treatment is recognised as having faile The conditions are now much less favourable f further treatment, as the growth has extended a wider zone and the cancer cells may have acquire tolerance to the radiation. If further treatment decided upon, it is clearly useless to give the sam treatment again; either a heavier dose of radiatio must be given or the treatment must be appli to a different zone. For the benefit of subsequen cases the reason for the failure must be carefull sought, and the original technique critically examine to see if it can be improved. As a matter of fac

such heavy doses of radiation are now given that it is usually impossible to repeat the original treatment, and it is comparatively rare for the growth to recur at the zone treated. Any recurrence is usually at the edges or beyond. Recurrence at the original site generally means faulty distribution of the radium or inadequate dosage.

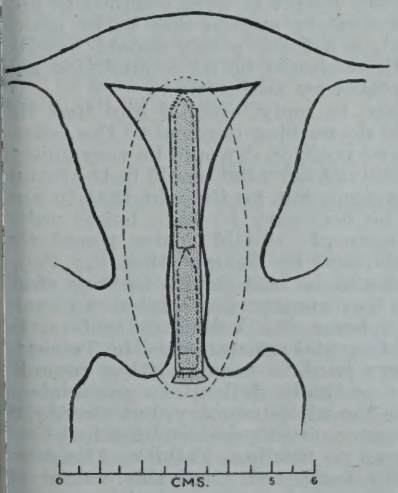
The success of radium treatment in cancer of the cervix depends upon the fact that for many months the disease is a local one. It involves a region which is accessible, and one to which a heavy dose of radiation can be safely applied if special precautions are taken. When the disease has spread widely to the deeper structures of the pelvis it is doubtful whether any form of radiological treatment can prevent the cancer cells from growing. It is a common but erroneous idea that it is possible to sterilise the whole of the pelvis. As a matter of fact, the dose of radiation required to kill cancer cells is so heavy that if it were applied to any large region of the body the patient would die. The treatment with heavy doses has, therefore, to be limited to a comparatively small field.

The most serious objection to radium therapy is that it fails to treat pelvic lymphatic glands. They are only involved, however, in about 37 per cent. of these cases at the time of death, and as the majority of patients are first seen a year or 18 months earlier, it is reasonable to suppose that the greater number of patients when first seen have no gland involvement at all. This is supported by the fact that many cases are alive and well ten years after radium treatment. The truth can only be determined by statistics on a large number of cases. Clinicians state that they often find glands involved at operation, but this is not convincing to a pathologist. It is a common error, even after microscopic examination, to mistake enlarged glands of long standing inflammation for glands involved with growth.

Distribution of the Radium.

The range of the effective action of radium tubes and applicators is so limited that the position in which they are placed in relation to the growth and to each other determines the results. Fig. 1 shows approximately the effective range of a tube applicator containing 50 mg. of radium element placed in the cavity of the uterus for 48 hours. This is roughly an ellipsoid; its length, size, and shape depend upon the length of the applicator and on the amount and distribution of the radium. The size increases with longer exposures, but only to a very small extent. When this ellipsoid is compared with the zone usually involved by a carcinoma, it is evident that a single tube, however placed, can only rarely, if ever, treat the whole region affected. Single tube applicators have now been universally discarded in modern methods of technique.

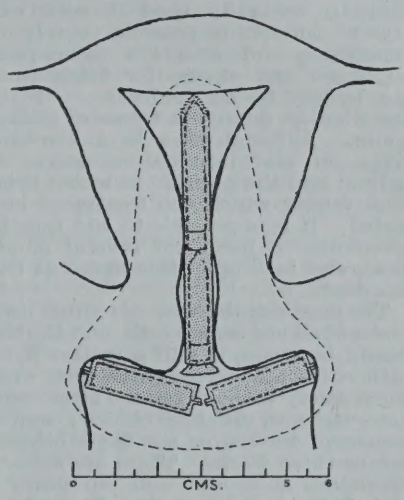
FIG. 1.



Shows the zone of effective radiation when a single applicator containing radium tubes is inserted into the cavity of the uterus.

It is therefore essential to use multiple sources of radiation at the site of the growth. When two or more radium applicators are placed near to each other, the adjoining tissue receives radiation from them all, and the dose is then the sum total which reaches a given spot from every source of radiation. This dose depends upon the amount of radium, its distribution inside the applicator, the distance it is away, the filtration, and the absorption of the intervening tissues. Fig. 2 shows the range of effective action when a central tube containing 50 mg. of radium element is placed in the uterine cavity, and three flat applicators, each containing 25 mg. of radium element, are placed in the vaginal vault for 48 hours. The size and shape of the cone vary with the condition of the cervix, for the size of this determines the plane in which the flat applicators can be placed. It is at once obvious that this method of distribution offers a much better prospect of treating carcinoma of the cervix successfully than does the use of a single tube applicator. The distances of effective action from the sources of radiation are based on experimental biological tests. I am indebted to Prof. Russ for adding the dotted lines to these diagrams, and to the Cancer Research Committee, of the London Association of the Medical Women's Federation for allowing me to reproduce them from their first report.[2]

FIG. 2.



Shows the zone of effective radiation when cross firing is obtained between an intra-uterine applicator and flat applicators in the vaginal vault.

One of the most important points is that the wider this cone is made at its base, the greater will be the prospect of saving the patient's life; it is therefore necessary to stretch the vault of the vagina to its widest capacity. Clinicians find it far easier to insert a small applicator than a large one, and they often pack radium tubes closely to the cervix, with the result that they obtain a more intense but smaller cone of radiation, and the outlying parts of the growth are ineffectively irradiated. The results are correspondingly poor. At the Fondation Curie (Régaud), although a somewhat different method is used, this point is recognised. Two radium applicators are attached to a spring which keeps them as far apart in the vault of the vagina as the space will allow.

It is impossible in this paper to go into details of the many other methods of distribution of the radium which are now employed at different clinics. A method very similar to that shown in Fig. 2 has been used in Stockholm (Forssell Heyman) for the last 15 years, and a similar method has been used in Japan (Ikeda) since 1914; the results are some of the best on record. This method has only been used in England since 1925 at two London clinics, and, as far as I know, it is not in use at the present time anywhere else in this country. The largest number of cases treated by this method and recorded in our own literature have been treated under the auspices of the Cancer Research Committee of the London Association of the Medical Women's Federation. They report [3] 117 cases with no death directly due to the treatment. Fifty per cent. of their cases treated more than a year ago are stated to be free from signs and symptoms of cancer; the percentage operability of these cases was not more than 15 per cent. These results are too

recent to justify conclusions as to the ultimate value of the method, but as far as they go they agree with the foreign reports and compare very favourably with the results at those clinics which report 70 per cent. of cases as having died within a year of the patients first being seen.

Dosage.

The question of dosage is as important as the method of distribution. All clinics recognise that their early work was done with inadequate doses. Radium was known to be dangerous and the clinician naturally used it with caution. At the present time it is possible to rely on wide clinical experience and scientific technique, and there is no longer any excuse for using small doses which are known to be ineffective. It is customary to describe the dosage in terms of milligramme element hours. Although this is a convenient method it gives no real information unless the amount of radium and the position in which it is placed and the time during which the treatment is carried out are stated. It is impossible to add together all the doses given over a period of several months, as is often done, and look upon this figure as truly representing the dose.

The most suitable dose of radium needed to cause the death of all the cancer cells, and the time in which this should be given, is still a matter for research. Most authorities are agreed that 7000 m.e. hours can be given safely without serious after consequences. The time varies in different clinics; some give the whole treatment in five or six days, others spread it over two or three weeks. There are a few cases on record which are alive and well ten years after treatment with 3000 m.e. hours, but it is almost certain that the clinics which reduce their routine dosage to this amount also reduce the percentage of their successful results. The object of the treatment is to give, as far as possible, a uniform radiation to the whole region involved by the disease and only to give just enough to prevent the cancer cells from living. If this is achieved the connective and epithelial tissues which ultimately replace the growth are not seriously damaged.

General Technique.

In this very short account of an intricate subject it is impossible to consider many important details. For example, the failure to pack off a radium applicator and to appreciate its range of most intense action may result in the normal bladder or rectal mucous membrane receiving an intense exposure; long-standing and distressing symptoms and fistulæ may result. If the bacterial infection which is so commonly associated with this type of case is not treated, the insertion of the radium tubes may set up an acute pelvic abscess. Many of the immediate deaths are due to this. A uterus involved with soft friable growth with an orifice difficult to find can easily be punctured by inserting radium. All these risks, which are very real, become practically negligible in the hands of a competent clinician trained in this very specialised field of work.

Conclusion.

It has been conclusively proved that for the large majority of patients suffering from cancer of the cervix modern radium treatment can completely replace surgery and give equally good and long-standing results; the immediate risk of the radium treatment is practically nil. The lives of many women, quite hopeless from the surgeon's point of view, have been saved for ten years and more. The treatment can often relieve distressing symptoms even when it does not save life; there is some evidence that it can prevent fistula formation.

The success of this treatment entirely depends upon the use of a scientific technique, and it requires a skilled gynæcologist specially trained in the work. Without this radium is often dangerous and is practically always useless as a means of saving life.

Very few women in this country can obtain this modern radium treatment, and many of our leading hospitals are entirely without the facilities for providing it. With extended knowledge it is to be hoped that this state of affairs will very soon be rectified.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

SCOTTISH HOSPITAL POLICY.

FUTURE relations between voluntary hospitals and local authorities in Scotland are none too easy to define, but their course has been made clearer by Sir John Gilmour's replies to a recent deputation from the Scottish Regional Committee of the British Hospitals Association. In introducing the deputation, Colonel J. A. Roxburgh said that there was an estimated shortage of 3600 hospital beds in Scotland, and while the voluntary hospitals wanted to coöperate with the public authorities, they felt it necessary to have a lead from the Government on the methods of coöperation, especially in view of the proposals for Poor-law reform. Colonel D. J. Mackintosh, for the deputation, then asked the following questions:—

(1) Is it proposed to establish a unified hospital service in Scotland?

(2) If the answer is in the affirmative, would the statutory hospital service cover the whole field of medicine and would it work in competition with the voluntary hospitals?

(3) Who is to provide the necessary additional beds after the present building programmes of the voluntary hospitals are completed?

(4) Will the voluntary hospitals and the public authorities work in coöperation round the voluntary hospitals as centres?

(5) Is it proposed to give financial aid to the voluntary hospitals, as recommended by the Mackenzie Committee?

(6) Is there any need to establish a statutory general hospital service?

It would be a public disaster, Colonel Mackintosh said, if the voluntary hospitals were crippled in any way, but if the voluntary system was to be maintained in Scotland, a definite policy should now be declared so that there should be no competition and rivalry with the statutory authorities.

Sir John Gilmour, in reply, assured him that the Government would do nothing inimical to the voluntary hospitals, whose position it would be very unwise to disturb. He could not say what would be the future of the Poor-law system, but he thought that in any scheme it would be necessary to have larger units. Coöperative arrangements should centre round the voluntary hospitals, and he thought that the Poor-law institutions should be brought up to their standard. Whilst the Government was anxious to avoid doing anything to harm the voluntary system, he could not promise financial assistance as the Treasury were finding it very hard to meet existing commitments. It was exceedingly difficult to enunciate a common policy for the whole country, but already in Scotland some advance on coöperative lines had been made in such places as Stirling, Falkirk, Aberdeen, and Glasgow. He suggested that the voluntary hospitals should appoint a small committee to act as a link between the regional committees and his department. This might be very helpful in solving regional difficulties.

The Position Considered.

Probably the hospitals will be disappointed with the Secretary of State for Scotland's reply to their six questions. But it is obvious that the answer to those questions depends on two main factors—namely, (1) public opinion about the proper use of the Poor-law hospitals, and (2) the necessity for a large increase of beds in the voluntary hospitals if they are to meet the ever-increasing demand for

accommodation. A Government grant is out of the question; how to tackle the Poor-law is not yet determined, in spite of 20 years' discussion and agitation; and meanwhile the Poor-law and the public health hospitals must face the statutory duties imposed on them.

Judging by the published report of the conference with the Secretary of State, the Hospitals Association does not seem to have considered the important fact that public health hospitals are now obliged to provide for large groups of diseases that formerly would have fallen to voluntary hospitals. Again, notification of the pneumonias, for instance, has brought to the public health hospitals thousands of cases that five years ago would never have found their way into any institution. The voluntary hospitals, although they do a great deal, are incapable of dealing with epidemics of pneumonia; still less can they provide for the equal, perhaps greater, epidemics of bronchitis, for which hospital treatment is increasingly demanded. The next big new field will be early rheumatism in children and adolescents, and within a few years (say five) these cases will run into thousands as the pneumonias have done.

The voluntary hospitals confine their attention too much to the work they themselves are doing. Only a few years ago they were treating almost all the tuberculosis cases that received any treatment at all. After tuberculosis became a notifiable infection, the numbers rapidly outran all voluntary capacity, and to-day nothing short of the resources of the local authorities can look at the problem. The death-rate continues to fall, but the cases in hospital and sanatorium continue to increase. Thus it appears that the hospital problem is being forced forward because new fields of disease are being systematically explored. The questions put by the voluntary hospitals are relevant enough if we are to assume that those hospitals have reached the limit of their activities and can be regarded as static. But this is what we cannot assume. The voluntary "principle" is safe enough, for a large section of the community prefers the voluntary method of providing for certain forms of disease, and the great medical schools will maintain their control, for the whole community wishes that they should do so. But the fresh waves of cases will not stop, and all the available hospitals will be compelled to adjust themselves to one another. Whether we call this process of adjustment "coöperation" or not, matters little; the process is going on rapidly and is inevitable.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Notification of Infectious Disease.

IT is notorious that the notification of infectious disease has been slackly carried out in Ireland at all times. This has been due to several causes. In the first place, until 1925 notification was only compulsory in certain areas, and therefore it was not recognised as a pressing duty. Further, in rural areas the notification would generally have been furnished by the dispensary medical officer, as medical attendant, to himself, as medical officer of health. Again, as there was no effective system of public health administration, no administrative steps were likely to follow notification. Both the local authorities and the practitioners, knowing the futility of notification from the practical point of view, acquiesced in its neglect. In 1925, however, the Local Government Act made compulsory throughout the Irish Free State the notification of certain infectious diseases—namely, small-pox, cholera, diphtheria, membranous croup, erysipelas, scarlatina, typhus, typhoid, relapsing fever, continued fever, and puerperal fever. Comparatively little attention seems to have been paid to this provision, the local authorities taking no steps to enforce it. In these circumstances the Minister for Local Government and Public Health thought it proper last week to issue a circular letter to all sanitary authorities to draw attention to their duties in the matter. He observes that a correlation of the statistics of registration of deaths with those for notification of infectious disease shows that notification is insufficiently performed. It should be realised, he says, that notification is not only essential for the protection of the public in facilitating disinfection and other precautionary measures, but in the interests of the individual patient enables the medical officer of health to assist in arranging for suitable institutional accommodation and nursing attendance where necessary. He suggests that general notice of the duty of notification and of the liability to penalty in case of default should be given by the sanitary authority to members of the medical profession and to the public at large by advertisement in the local press and such other means as may be considered advisable. When a county medical officer of health is appointed he will receive the notifications, as is necessary if he is to perform his duties effectively.

Certification of Insured Persons in the Free State.

The present system of remuneration for certification of insured persons under the National Health Insurance Acts has been working since the beginning of 1916. Under it the funds available for payment in rural areas are distributed to the members of the profession on the basis of a pool for each dispensary district. The pool is divided among the several certifiers entitled to share in it in proportion to the work done by each. The National Health Insurance Commission has now notified the Irish Medical Committee of its dissatisfaction with this arrangement. It is said that serious anomalies have arisen in some counties owing to considerable divergence in the rates of payment in adjoining areas. Furthermore, the cost of administering the present scheme is said to be greater than the Commission thinks justified. The Commission proposes, therefore, to substitute a county pool for the dispensary district pool as from Jan. 1st, 1928. Such a change is likely to require consideration as many of the country practitioners were insistent, at the time the scheme was drawn up, on the dispensary district pool.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

Actinomycosis in Bessarabia.

THE district medical officer in Czernowitz has been investigating some cases of human actinomycosis near the Bessarabian border. The seven which he examined were nearly all infected on the face and neck, and in each the clinical diagnosis was confirmed by microscopical examination of the pus. If to these seven are added three others observed by a colleague in Chisinew, the total number of cases reported from mid-eastern Europe becomes 46. In 24 the infection was limited to the face and neck, whilst in the remainder the viscera were attacked. The district officer has collected some 250 cases from the literature, both at home and abroad, and deduces that the cutaneous forms cause death in only 2 or 3 per cent. of cases. In cervico-facial actinomycosis the mortality is, he says, 10 per cent., rising to 30 when the disease is deeply seated in the temporo-maxillary region, and to 50 in submaxillary infections, which are fairly common as a result of straws being used for picking teeth. The death-rate in abdominal actinomycosis of intestinal origin he gives as 65 per cent., and there are only about 15 per cent. of recoveries when the liver or cerebro-spinal system is attacked. Presumably these figures refer to the condition found when the patient first comes for examination.

Demoralisation of Children.

A Rumanian judge has been saying to the Child Study Association that in all the large cities of this

country children are surrounded in the streets by dirt, miserable dwellings, cold, illness, starvation, and famine. Life on the streets is undisciplined, and prostitution is carried on openly. He has fought, he says, for ten years for the erection of a detention home for young delinquents, where they may be segregated from adults by whom they are taught immorality and hatred of work. Years ago he suggested the establishment of a special police force to look after children, but the plan has remained nothing more than a plan. He estimates that 30 to 40 per cent. of the young women are infected with venereal diseases, so that in some cities the police refrain from making raids because the hospitals cannot accommodate the vast numbers of patients they would gather. Among the causes of low moral standards are adverse family conditions and unemployment, together with alcohol, the primitive intelligence of parents, and the neglect of children by those who go out to work. Advocating the development of a social policy and a radical improvement of housing, he pointed out at the same time that if the next generation is to be properly educated fewer criminals and prostitutes must be permitted in their midst.

Salvarsan in Tabes.

Discussing the treatment of tabes at a recent meeting of the Cluj Medical Society, Dr. Elfer said that the danger of salvarsan as a spirillicide is that it may destroy the weaker strains of parasite whilst stimulating the more resistant. This is what happens, he thinks, when an inadequate course of treatment is given, and such a course is more damaging than none at all. It is useless to give one or two injections of salvarsan at a time, repeating the dose at half-yearly intervals. If the drug is to be used at all, the injections should be made at intervals of five to seven days, and eight or ten are needed in each course. The doses, in his opinion, should not be more than 0·45 g., and the whole quantity should not exceed 4 g. The course can be repeated two or three times with intervening rests of five or six months. It is as well to remember, however, that as much harm can be done by giving too much salvarsan as too little, for it may cause changes in the blood-vessels and even lead to cerebral hæmorrhage. In tabes Dr. Elfer does not, as a rule, use neosalvarsan unless the patient has had no treatment with it—or inefficient treatment—before the tabetic symptoms come on. In such cases combined courses of mercury, bismuth, and neosalvarsan may give fairly good results. One method of employing the arsenic compounds (American in origin) is to give one weekly injection of salvarsan for 100 consecutive weeks. Dr. Elfer has given this plan a trial and finds it very efficacious because it allows the patients to go on with their work. Alternatively, injections of 4 to 5 mg. of neosalvarsan may be given intraspinally, and Prof. Gennerich gives 20 or 30 such injections in succession. In such small doses, however, the drug has little or no effect on the spirochætes, and if the quantity is larger it may cause severe poisoning. Therefore Dr. Elfer does not approve of the method —apart from the fact that few patients are ready to have 15 to 20 intraspinal injections.

MANCHESTER PATHOLOGICAL SOCIETY.—At a meeting of this society held on Dec. 14th, with the President, Mr. F. H. Westmacott, in the chair, Dr. W. Susman read a paper on the relation of the spleen to immunity. He referred to the work of many observers who had indicated that the reticulo-endothelial system and the spleen in particular had to do with the production of immune bodies. It might be assumed, he thought, that the pulsations of the spleen were an indication of its function. These pulsations, as shown by Schafer, were inhibited by atropine and augmented by injections of brain extract. In a small series of rabbits the subcutaneous injection of a boiled watery extract of brain tissue had enhanced the process of agglutinin formation against *B. typhosus*. The administration of the same extract to a large series of mice, infected with pneumococcus type 1, had shown a survival of 51 per cent. of a total of 262, after a similar number of control animals were all dead. The survival extended over 2 to 3 weeks and, in several experiments, to 5 to 8 weeks, when the experiments were concluded.

Public Health Services.

SANITATION OF THE PORT OF LONDON.

Dr. W. M. Willoughby, in his report for 1926 mentions that in that year no case of plague or cholera reached the port, that no plague-infected rat was found nor was any suspicious rat mortality observed in the docks or on ships. Arsenious oxide found on apples never exceeded 1/30 gr. per lb. Considerable progress has been made in the changing of the sanitary conveniences of the port to water carriage. One pavilion of the Denton (near Gravesend) Port Hospital for infectious diseases requires renewal. These are the salient points in the report, and the Port of London is to be congratulated upon their non-sensational character, although the medical officer may miss the epidemics of plague and small-pox which made such good reading in former years. During the year 348 cases of infectious diseases were notified within the port with 16 deaths; respiratory tuberculosis, 71 cases (8 deaths), of whom the Seamen's Hospital Society took charge of 30, as well as of 9 of 15 pneumonia cases and 9 of 41 cases of malaria. There were 22 enteric cases with 1 death; diphtheria 12 cases (2 deaths), 4 from ships, 5 from *Exmouth*, and 2 from other training ships. In the disinfection of ships sulphur fumigation and washing down with disinfectant seem to give satisfaction, provided infected articles are removed for steam disinfection. There were caught and destroyed 24,130 rats, half in docks warehouses, half on board ships; of the 2106 examined most of them brown rats, none was plague-infected. One colony that could not be otherwise dealt with was besieged and its water-supply cut off; then juicy cabbage leaves became an acceptable bait, and the place is now practically rat-free. It must always be remembered that sulphur fumigation involves risk of fire. Zyklon B. contains tear-gas as a warning against its hydrocyanic acid, but its warning must be treated with respect; on an occasion mentioned one man took the warning and escaped; the other, in charge, tried to go on too long unprotected and died. Carbonic acid is another danger; a ship's officer, working in a baggage room, dropped his keys into the hold below and incautiously went down for them. He was overcome and the lascar who tried to rescue him also died. This hold contained bales of skins and polished rice, both oxygen-absorbing, also live mustard-seed and ground nuts, oxygen absorbing and carbonic-acid producing. Over 20,000 ships entered the port in the year; of the foreign-going ships, 15 per cent., of the coasting, 12½ per cent. had sanitary defects. The cost of maintenance of each patient in the port hospital was £1 18*s.* 8*d.* for an average stay of 15·7 days. Food inspection is the greatest sanitary work of this port, over 4000 tons were destroyed in the year or disposed of specially, more than half being exported. The work of the authority has been greatly increased by the new control of fats, of which 71,108 casks were imported besides 15,107 casks of "edible tallow" (whale oil). Actinomycosis compelled the condemnation of 7½ tons of beef tongues, about 1 per cent. (last year 2 per cent.). The general state of pig carcasses entering the port was found to be excellent. A cargo of chilled beef was imported from Australia in July; as the beef is not frozen there is no crystallisation of muscle substance, and while the growth of moulds, &c., is just checked, every process of manufacture requires a very high degree of cleanliness, an obvious gain to the consumer. Of 16,119 ships 13,611 of them seagoing, 1265 had dirty quarters, 68 leaky decks, 64 bad w.c.'s, 58 bad lighting, 55 bad ventilation, 53 bad heating. A case of discharge of foul water into the river was dealt with and 128 nuisances on shore premises. Of 34,034 aliens arriving 28 were found to be suffering from infectious and other diseases. At the end of the report is an appendix on the state of the canal boats, which appear to be in good order.

AN OUTBREAK OF ACUTE POLIOMYELITIS.

IN Byrom Bramwell's "Diseases of the Spinal Cord" 884 edition) infantile paralysis is said to be a rare ndition in the adult, and no suggestion is given that may occur in epidemics or may be spread by infec-on. Sporadic cases were in fact the only form then own, but nowadays it is recognised that there may epidemics over wide areas, either with no apparent nnexion between the cases or with links which can clearly traced. The epidemics in Leicester and icestershire in 1926 were examples of the former nd, whilst an outbreak of the latter variety is scribed by Dr. Bernard Wood-White in his 1926 port for East Suffolk. This outbreak (which sembles the one in the little village of Stoke Rivers, evon) occurred in the village of Dennington, which s a population of about 600. There were 15 cases cluding abortive ones with four deaths. In most ses the medical attendant was Dr. C. W. Wylde mstrong, of Framlingham, and in coming to a nclusion as to the nature of the abortive cases Wood-White and Dr. Armstrong were in con-ltation and in agreement. The following is a brief tory of the cases. Each case is indicated by a ter (or two letters for the second case in a house), d the sex and age are given in parentheses.

A. (f., 16), domestic servant at Kensington, left her ne at Dennington August 12th with a headache, died gust 14th at her place in Kensington. The cause of death s certified after post-mortem examination as "encepha-s (acute)." The subsequent history of the outbreak wed that hers was a case of poliomyelitis.

A. B. (m., 3), brother of A.; began August 20th; recovered gust 23rd; abortive type. Five family contacts aged 43, 15, 13, and 10.

B. (f., 22) lived 200 yards from A. B.; began Sept. 3rd; l under treatment; transverse myelitic type. Two ily contacts aged 68 and 59.

C. (m., 4) lived in a village three miles off; began t. 18th; recovered Oct. 1st; paralytic type with int. Seven family contacts 46, 47, 12, 11, 9, 8, and 5.

D. (m., 17) began Sept. 25th; paralytic type; still under atment.

E. H. (m., 13 m.), brother of E.; began Oct. 1st; died . 6th; paralytic type. Six family contacts of E. and H. 56, 38, 13, 8, 8 (twins), and 7.

F. (f., 9) began Sept. 29th; died Oct. 1st; paralytic e. Eleven family contacts aged 42, 40, 15, 14, 12, 10, , 4, 2, and 5 months, of whom four had diarrhœa on t. 29th.

G. (f., 22) began Sept. 29th; died Oct. 5th. Three ily contacts 55, 53, and 15.

H. (m., 13) began Oct. 6th; recovered Oct. 28th; paralytic . Four family contacts 54, 51, 18, and 15.

I. (m., 15) began Oct. 7th; recovered Oct. 13th; abortive e.

J. M. (f., 5½) began Oct. 12th; recovered; abortive type. family contacts of J. and J. M. aged 44 and 42.

K. (m., 12) began Oct. 9th; recovered Oct. 18th; abortive . Five family contacts aged 49, 59, 30, 23, and 14.

L. (m., 6) began Oct. 9th; recovered Oct. 16th; abortive e.

M. (m., 13) began Oct. 13th; recovered Oct. 19th; tive type. Two family contacts aged 56 and 45.

N. (m., 7) began Oct. 19th; still under treatment; para-type; lives next door to K. Six family contacts 44, 47, 18, 13, 11, and 3.

he epidemic lasted ten weeks. The first cases nd A. B. occurred in the Badingham-road and t of the other cases occurred in a cluster of ages in the same road about half a mile away. Wood-White assumes that all those under the of 30 are susceptible and the rest immune, and 18 per cent. of the susceptible persons in the ll area of the Badingham-road contracted the ase. There was one family with two paralytic s; a second with a paralytic and an abortive, and ird with two abortive cases. In the four cases re the source of infection was identified with e probability the incubation periods were 6, 7, 9, 11 days respectively.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1926 statistics of 11 districts of varying local government status :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality from childbirth.
East Ham C.B... (146,600)	17·1	9·6	0·96	1·35	1·6	1·2	8·4	56	2·0
Woolwich M.B... (141,900)	17·4	10·2	1·16	1·39	1·6	1·3	5·3	43	2·4
Ealing B. .. .. (91,783)	14·0	10·1	0·86	1·53	1·6	1·6	3·9	55	3·1
Wigan C.B. .. (88,620)	20·0	13·1	0·93	0·91	3·6	1·0	9·6	103	4·5
Southport C.B. .. (77,970) ..	11·9	11·9	0·56	1·58	1·7	1·7	5·4	62	5·4
Warrington C.B. (77,280)	20·5	11·6	1·42	1·07	2·6	1·6	16·3	86	3·1
Heston and Isleworth U.D. (51,240)	17·4	9·7	0·86	1·39	1·3	1·4	5·5	56	2·2
Eccles B. .. .. (45,670)	17·0	11·5	0·91	1·48	2·1	1·5	9·0	78	5·1
Dover B. .. .. (39,780)	17·6	11·1	1·30	1·60	1·7	1·2	2·7	68	4·0
Leamington Spa B. (30,040)	13·6	14·6	0·73	2·26	2·0	2·4	14·6	76	9·7
Chelmsford B. .. (22,800)	15·4	10·2	0·79	1·40	1·2	1·5	2·8	68	0·0

C.B. = County borough. M.B. = Metropolitan borough. B. = Borough. U.D. = Urban district.

East Ham.

Dr. W. Benton reports that the maternity and child welfare department is doing excellent work, but that it is still handicapped by under-staffing. During the year arrangements were made for the school ophthalmic surgeon to see eye cases referred to him from the infant welfare centres. One ante-natal clinic is held weekly and in addition to this the East Ham mothers attend the antenatal clinics of the Plaistow Maternity Charity and Queen Mary's Hospital, Stratford. The borough has no maternity home. The ophthalmic surgeon, Dr. C. L. Gimblett, reports that the cases of defective vision have to be kept under special observation. Parents are reluctant to allow their children to be sent to residential "myope" schools and there are no "myope" classes in East Ham. During the last half of the year he saw 39 cases among the pre-school children, divided into three groups. There were 29 cases of incipient squint, 8 cases of acute conjunctivitis, abscess of the tear duct or corneal ulcer, and 2 cases of congenital malformation of the eyes, all of which will derive great benefit from treatment at the earlier age. There is only one school dentist, and Dr. Benton reports that there is need for at least two more in the borough, and that no real preventive dentistry can be undertaken until they are appointed. Housing conditions are still far from being satisfactory. The new houses erected during the year numbered 347, of which 24 were municipal. Dr. Benton refers to the scandalous overcrowding on the District Railway during the early morning and evening, and regards this as a means of spreading infection during influenza epidemics.

Woolwich.

Dr. J. Macmillan reports that houses are being erected in increasing numbers each year. Of the new ones in 1926 203 were built by private enterprise and 170 by the Council; this was more than in any previous post-war year, but was still behind the yearly average before 1914. The hutments are still used as permanent homes. They were erected as a temporary expedient and have outlived their purpose and require more and more attention to maintain them in habitable condi-

tion. A few Woolwich residents have obtained houses on the London County Council estates outside the borough and the erection of 170 houses during the year on the borough council's Eltham estate has done something to ease the housing situation; but more accommodation is required, and no action can be taken to close "unfit" houses.

One of the events of the year was the opening of the new Plumstead infant welfare centre, a plan of which is given in the report. The opening of this centre marks a new departure in the unification of the London health services, as from 1927 onwards it will be used by the L.C.C. for a school dental clinic, capable of treating some 1400 children. The new centre has also been found far more suitable for sewing-classes and the like than the room formerly used at the old town hall. The council's scheme for the orthopædic treatment of pre-school children works satisfactorily and is expanding. These children are sent to the remedial clinic of the Woolwich Invalid Children's Aid Association and fees are paid by the council for each attendance. The total cost for 1926 was £191 4*s*. 6*d*. The borough has no maternity hospital, but pays £1500 per annum to the British Hospital for Mothers and Babies for the admission of 144 cases recommended by the medical officer of health. Payments are made by the patients according to their means and during the year nearly £600 was recovered in this manner. This hospital conducts an antenatal clinic which was attended by 960 mothers during the year. The births in the borough numbered 2463.

Ealing.

Dr. Thomas Orr's report is largely taken up with a description of the arrangements for dealing with the added areas. The urban district of Hanwell contained about 20,000 and that of Greenford nearly 2000 persons. Owing to the insufficiency of the Greenford Council's staff many things required attention, among others a grossly polluted tributary of the Brent had to be dealt with; Greenford's sewage disposal works were inadequate, and proposals have been made for its extension. Pail-closets had to be converted into water-closets; and sanitary dustbins for houses to be provided. The destructor at Hanwell needs enlargement. The maternity and child welfare and school medical services have been extended so as to include the two new areas; two new centres have been established; a whole-time school dentist will take the place of a part-time one, and a full-time woman assistant medical officer will take the place of part-time officers. During the year 819 houses were erected of which 100 were municipal. Before the extension no milk was produced in Ealing, but Greenford brought in six cowsheds. One was an up-to-date well-managed dairy farm, one is being reconstructed, but the other four will need much attention in order to comply with the Milk and Dairies Order, 1926.

Wigan.

Dr. Henry Whitehead says that greater interest is being taken by expectant mothers in antenatal work. During the last three years the number of expectant mothers attending these clinics was 210, 254, and 489 respectively. The total births in Wigan last year were 1775. Dental treatment was given to 39 mothers and 76 children under 5. A card is kept for each year of life up to 5 and a final record and history is passed on to the school medical officer. Far greater coöperation than formerly exists between the medical practitioners and the clinical tuberculosis officer. Consultations are frequent and many cases are sent to the dispensary for diagnosis. In Wigan, as elsewhere, however, patients with suspicious symptoms do not consult their doctors early enough. The scheme for the conversion of the conservancy closets to a modern system makes good progress. In March, 1923, there were in the borough 8234 water-closets, 840 waste water closets, 7081 pail closets, and 1563 privy-middens. At the end of 1926 there were 18,317 water-closets, 811 waste-water closets, 730 pail-closets, and 274 privy-middens. The scheme for converting the waste-water closets to ordinary water closets only began in April, 1926. A nuisance has been caused by the Miry-lane depôt, in the centre of the town, which has for years been used as a dumping ground for privy contents, and the time has come, says Dr. Whitehead, when all the refuse should be incinerated.

The housing shortage is still acute and no progress can be made in dealing with insanitary dwellings or areas, except repairs of a very temporary nature. Dr. Whitehead draws a terrible picture of the environment in which children exist in several parts of the town, and shows how the bad environment and bad habits react upon one another. All this is intensified by the crisis through which the chief industries of the town have passed during the last few years. Inability to maintain additional babies leads to an increase in the practice of criminal abortion, either by drugs or mechanical means. He suggests that there should be far greater vigilance and a service of detectives to cope with this evil, but he shows that the real remedy is of course to secure better houses, more open space in congested areas, and a better environment in every respect. The health department in Wigan has, in fact, a very difficult task before it.

Southport.

Dr. G. C. Barnes alludes to the typhoid carrier problem and thinks there is an urgent need for more radical powers to deal with it. He gives one example. In December, 1920, and January, 1921, the two grandchildren of a "carrier" were admitted to hospital for typhoid fever. A nurse at the hospital contracted the disease. In July, 1926, a person who lodged with the carrier was admitted to hospital and died from typhoid fever. The carrier herself was also admitted to hospital for observation. The nurse, in charge of the carrier at night, contracted the disease and died. In September another lodger from the carrier's house was removed to hospital suffering from typhoid and recovered. On Nov. 13th the carrier was certified as insane and removed to an institution.

Dr. Henry Bardsley reports that the venereal diseases scheme progresses satisfactorily. During the year five women patients were confined and in each case apparently healthy babies were born. Final tests were applied in the case of ten men who came up for examination before marriage. Dr. Bardsley thinks there should be greater powers to deal with women who are in an infectious state and will not submit to treatment. He cites three or four who have been the cause of disease in 23 men. One of these women was admitted for confinement and the child had congenital syphilis. She took her discharge and had failed to attend the clinic for treatment. Another suffering from both gonorrhœa and syphilis had attended the clinic on one occasion only. Dr. Bardsley estimates the cost of in-patient days and out-patient attendances of the 23 men infected by this small group of women at £320.

The obstetrician in charge of the antenatal clinic, Dr. A. S. Garden, reports that the attendances are increasing and good results are being obtained. Among those who attended the clinic there was no case of eclampsia; there was no reason to use high forceps; in several cases labour was induced before full term to avoid difficult labour, and all did well. there were seven cases of Cæsarean section, six due to contracted pelvis; three cases of breech presentation were converted and all the occipito-posterior presentations were corrected before labour.

The hours of sunshine during 1926 totalled 1474·

Warrington.

Dr. G. W. N. Joseph shows that of the 17 large towns of Lancashire only Blackpool, Southport, Bury, and Barrow-in-Furness had a lower infant mortality during 1926 than Warrington. Antenatal clinics are held at three centres and were attended by 522 expectant mothers. The number of births in the borough was 1591. One of the antenatal clinics is held at the maternity home, in which 248 women were confined during the year. There were no maternal deaths

11 stillbirths, and six deaths of infants. Five operations for Cæsarean section were performed owing to contracted pelvis, and in each case the mother made a satisfactory recovery and living children were born (in one instance twins). The five deaths from childbirth which occurred in the borough were due to puerperal fever, 2; embolism of lungs, 1; chronic nephritis, 1; and lobar pneumonia, 1. The records show that during the last ten years 109 cases of ophthalmia neonatorum were notified. The damage done consisted of a case of total blindness in 1917 and a second in 1919. There were also seven cases of partial impairment of vision. The housing problem still remains acute although 74 new houses were built by the corporation and 437 by private enterprise during 1926. There are still 586 applicants living in overcrowded conditions. The following houses have been built by the corporation—40 wooden and 6 concrete and 275 types A and B houses. Applications for municipal houses are dealt with by a subcommittee which endeavours to select the most urgent cases from the point of view of overcrowding—confinement expected, adults of opposite sexes in the same bedroom, husband living apart from family owing to want of accommodation. Almost the only group which can be dealt with are the lodgers in overcrowded houses. Up to date 137 corporation tenants have received permission to take lodgers.

Heston and Isleworth.

Dr. Elwin H. T. Nash reports that there is a lack of out-patient treatment for children in his district. He also reports a difficulty in getting the public water-supply for some of the developing districts in the western area. The mains, for example, run along the Staines and Bath roads, and in the intervening areas houses have to depend for their supply on surface wells. During the year the tip for house refuse in the Staines-road has caused an intolerable nuisance and a plague of flies. The situation was improved by the use of disinfectants and the nuisance appears to have arisen from want of care in covering the refuse with earth. Dr. Nash finds that the sanitary inspection of the district cannot be satisfactorily carried out owing to the inadequate staff of inspectors caused by the failure of the council to fill an existing vacancy. Nearly a million pounds has been granted in loans by the council under the Small Dwellings Acquisition Act and the Housing Act, but the result expected from the creation of a new class of owner occupiers, who would take a pride in their homes, has not been altogether achieved. This is largely owing to the practice of sub-letting. Dr. Nash also refers to the difficulty experienced by mothers of families in securing houses. The housing shortage has produced the problem of the van dwellers. Many of the vans are quite unsuitable for dwellings and the van dwellers are often a serious nuisance to the neighbourhood. Dr. Nash thinks more stringent powers are necessary to deal with van dwellers. Twenty-two cases of encephalitis lethargica were notified, some of which really arose in the previous year. Full case-notes are included in the report. There is no consulting obstetrician in the district, although Dr. Nash is convinced of the need of one, both in view of the importance of antenatal work and of the puerperal pyrexia regulations. In the school report the lack of an open-air recovery school and of an organiser of physical training are mentioned.

Eccles.

Dr. J. E. Spence reports that the filtration apparatus installed for the swimming baths has given satisfactory results. The bath was last filled on Jan. 6th, 1923, and the only new water added has been to replace wastage and to wash the filters. During the year the baths have been enlarged and the new swimming-baths have also been supplied with a filtration apparatus. Bell's patent filters have been adopted in both cases. There is a shortage of working-class houses. Only 108 houses were erected during the year, of which 72 were municipal. The corporation have now acquired practically all the property included in the S.E. Eccles improvement scheme, but they are compelled by the shortage to permit the continued occupancy of these houses. "Whatever may be reported about the shortage being overtaken," says Dr. Spence, "there are no signs of that happy position here." The Eccles house is ill adapted for sub-letting, and Dr. Spence sums up as follows: "The position of many of these people is intolerable. Compelled to occupy lodgings at prohibitive rentals, in many instances the accommodation afforded them is altogether inadequate. Families are living and sleeping in one room. In many cases parents and grown-up children have to share the same bedroom."

In June there was an outbreak of small-pox limited to four cases. Complete arrangements have been made to comply with the puerperal fever regulations. Dr. W. R. Addis, of Manchester, has been appointed consulting obstetrician, and in-patient treatment will be provided at Ladywell Sanatorium. Nursing assistance will be given by the health visitors, supplemented by additional nurses if necessary, and pathological specimens will be examined at the public health laboratory, York-place, Manchester. Dr. Spence refers to the importance of antenatal work, and a beginning has been made by a weekly meeting for expectant mothers, 93 of whom attended. The total births numbered 778.

Dover.

Dr. A. B. McMaster reports that owing to the operation of the new Meat Regulations it has been possible to determine the percentage of tuberculous animals slaughtered, and that 8·6 per cent. of the cattle and 1·2 per cent. of the pigs were found to be tuberculous. The new houses erected during the year numbered 109, of which 102 were municipal. No particular difficulty is being experienced in securing repairs to property. Four small insanitary areas have been represented, involving 79 dwelling-houses. Schemes have been under consideration, but, in view of the corporation's financial commitments, action is not likely to be taken in 1927. Immunisation for diphtheria is adopted for the staff at the isolation hospital and is also offered generally to the children in the borough, if the parents so desire. The Dover Medical Society is coöperating in the scheme. Scarlet fever antitoxin has been used for the treatment of a number of cases at the isolation hospital with excellent results, and clinical data will be furnished subsequently when a greater number of cases have been treated. The hours of sunshine totalled 1570·1.

Leamington Spa.

Dr. W. L. Goldie reports that building operations on the Rushmore Estate have made progress, and that the total of council houses has been brought up to 226. Tractors have been substituted for horse-drawn vehicles for the removal of refuse, and a motor ambulance has been provided by the council for the removal of cases of sickness or accident. The baths have been entirely renovated and various forms of medical baths provided. A filtration scheme has been adopted for the swimming-baths. The hours of sunshine were 1280·1.

Chelmsford.

Dr. R. H. Vercoe includes in his school report particulars of the new school. It will be a one-storey building, designed on the quadrangle principle, with a grass space in the centre and an open corridor round the inner side of the quadrangle to give access to the class-rooms. The accommodation is for 890 scholars. The windows of the class-rooms which face south are to be glazed with vita-glass. The plan and elevation of the buildings are included in the report. Dr. Vercoe has laid himself out for giving practical health lectures in the schools. The teachers were asked to make suggestions at the end of the lectures as to how the subject could be made clearer. A novelty in his report is the inclusion of essays written by members of his audiences, varying in age from 8 to 13, which showed that the writers had a good grasp of the subject ("sunlight").

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 17TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 212 (last week 230); scarlet fever, 1933; diphtheria, 1495; enteric fever, 67; pneumonia, 1522; puerperal fever, 38; puerperal pyrexia, 87; cerebro-spinal fever, 7; acute poliomyelitis, 10; encephalitis lethargica, 32; dysentery, 11; ophthalmia neonatorum, 98. There was no case of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (2) from enteric fever, 81 (23) from measles, 9 (2) from scarlet fever, 19 (8) from whooping-cough, 40 (7) from diphtheria, 56 (13) from diarrhœa and enteritis under two years; and 94 (17) from influenza. The figures in parentheses are those for London itself. The death from enteric fever outside London occurred in Birmingham. Of the fatal cases of measles 13 were notified from Bristol, 12 from Manchester; while the figures from Glasgow and Dublin for the same week were 29 and 8. The number of stillbirths registered during the week was 253 in the great towns, including 52 in London.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. S. F. St. D. Green, late R.A.M.C., retires on ret. pay.

Col. L. Humphry, late R.A.M.C., to be Maj.-Gen., vice Maj.-Gen. S. F. St. D. Green to ret. pay.

Lt.-Col. J. F. Martin, from R.A.M.C., to be Col., vice Col. L. Humphry, promoted.

Maj. H. W. Russell to be Lt.-Col., vice Lt.-Col. J. F. Martin, promoted.

ARMY RESERVE OF OFFICERS.

Lt.-Col. A. H. McN. Mitchell, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Lt. J. R. E. Sansom, from A.E.C., Reg. Army Res. of Off., to be Lt., and retains his present seniority.

TERRITORIAL FORCE.

Lt. A. M. Cooke to be Capt.

Second Lt. G. T. Hankey (late R.F.A.) to be Lt.

H. Watson to be Lt.

INDIAN MEDICAL SERVICE.

Maj. J. A. Shorten to be Lt.-Col.

Capts. R. C. Phelps and Byram Sorabji Dhondy to be Majs.

Lt. G. Dockery to be Capt.

Col. A. Fenton retires.

Temp. Capt. Subbier Annaswami resigns his temp. commn.

INTERNATIONAL CONGRESS OF SOCIAL WORKERS.—A bulletin issued by the Milbank Memorial Fund of New York states that 21 nations will be represented at the "first world congress of social workers," to be held next summer in Paris. It is estimated that there will be more than 1000 American delegates, and the participating groups will include the International Child Welfare Congress, the International Housing and Town Planning Congress, the International Congress of Public and Private Welfare, and the International Conference of Social Work.

THE LATE DR. T. W. CLAY.—Dr. Thomas William Clay, who died on Dec. 16th at the age of 58, started practice in Holyhead 33 years ago, and had long been medical officer of health for the Holyhead Urban District Council and port sanitary authority. A son of the late Commander Clay, he studied in the extra-mural school of medicine at Edinburgh, and took the Scottish conjoint diploma in 1891. On settling in Holyhead he became one of the best known doctors in North Wales, and held appointments as medical inspector of seamen, certifying factory surgeon, and deputy coroner, besides being medical referee of a number of insurance companies. He was also a justice of the peace for the county of Anglesey, and an Esquire of the Order of St. John of Jerusalem.

Correspondence.

"Audi alteram partem."

IS IT UNDULANT OR ABORTUS FEVER IN GREAT BRITAIN?

To the Editor of THE LANCET.

SIR,—I have read with great interest the paper by Dr. E. Wordley in your issue of Dec. 17th. The possibility of a prolonged fever of the undulant type arising in this country as a result of drinking milk infected with *Brucella abortus* has been a subject in which I have been much interested. The bacteriological evidence of the close relationship between *Brucella abortus* and *melitensis* is very strong, and it would seem that some cases of undulant fever in Rhodesia and in France cannot be traced to any source other than cow's milk, but as there is also a porcine strain of *abortus* it would be profitable to inquire whether some of the indigenous British cases of undulant fever cannot be traced to pigs. I have recently published a paper in a special number of the *Archiv für Schiffs- und Tropenhygiene* on two English cases, similar to those described by Dr. Wordley and Dr. J. Bamforth,[1] which have come under my notice during the last three years. In neither of my cases could any contact between the patient and goats or goat's milk be discovered. The first case was that of a county gentleman who owned a herd of cattle heavily infected with *abortus* and who partook of their milk (unboiled), in which the organism was actually proved to exist. He suffered from a typical attack of undulant fever which lasted three months. The blood serum in his case agglutinated *melitensis* 1 : 800 and *abortus* 1 : 1200. The second case was that of a gentleman who suffered from a prolonged febrile illness for over four months. He was proved to be a carrier of *B. typhosus*, but this was traced to a previous attack of typhoid fever and did not fully explain the nature of the present illness. In his case the serum agglutinated *abortus* 1 : 160 and *melitensis* 1 : 640. He had been drinking cow's milk obtained from the local dairy. I think little doubt can be entertained of the correctness of the diagnosis in these two cases and the significance of positive agglutination in a titre of 1 : 640, provided that the serum has been heated to 56° C. for half an hour previous to testing, can hardly be doubted. Personally, under the circumstances described by Dr. Wordley, I would accept a dilution of 1 : 400 as diagnostic. I recently have had under my care two unusually severe cases of undulant fever, one from Peru and the other a laboratory infection; in both instances the organism was isolated from the blood and also from the urine in the former, but in neither case will the blood serum agglutinate *melitensis* or *abortus* in a dilution higher than 1 : 80.

I am, Sir, yours faithfully,

PHILIP MANSON-BAHR.

Hospital for Tropical Diseases, Endsleigh-gardens, London, Dec. 21st, 1927.

RECURRENT COLDS.

To the Editor of THE LANCET.

SIR,—The fact that my own immunity from colds has been so remarkably consistent has led me to speculate why normal healthy people are so prone to catch them. In my opinion it is often because their clothes are grossly in excess of their actual needs, and I think that the subject of overclothing demands our serious consideration. The modern Briton, as soon as he is born, is promptly wrapped up in yards of woollens, and though it is, of course, true that the

[1] THE LANCET, 1927, i., 818.

heat-regulating mechanism of the human infant remains ill-developed for some time, this is no reason for continuing the wrapping-up process when the organism has become acclimatised to its surroundings. The ritual of mummifying babies is continued throughout childhood and adolescence, so that the skin very rarely comes into direct contact with air and light, its natural stimuli. Probably the whole tempo of metabolism is profoundly influenced by this air and light starvation, and a sudden change of temperature may suffice to cause a cold in people whose heat-regulating mechanism has been vitiated by unphysiological nursing.

As a matter of routine, therefore, the whole body should be exposed to the light daily, summer and winter, for a certain time, and no underclothing need be worn by normal healthy individuals. The adoption of this somewhat Spartan régime will raise the general tone of the organism and vivify every bodily function. This is a rule I have strictly observed for the past 15 years, during which time my immunity from colds has been well-nigh Olympian. I must add that I have done my utmost to catch cold by visiting the most virulent cases, but so far all my wilful attempts to infect myself have dismally failed. I still continue to discard underclothing throughout the year and I never feel the need for it in any weather.

Desiring to control this experiment I have on several occasions imprisoned myself in one of those popular "woollen combinations" and have sailed out in the open. As a result, both my temperature and pulse rose appreciably and my discomfort was so intense that I felt literally baked. I endured the inconvenience, however, but as my sense of well-being was markedly diminished it became clear to me that I had committed a grave physiological offence. On discarding the superfluous garments equilibrium was promptly re-established and efficiency correspondingly increased. No doubt if I had persevered I could have acquired a certain measure of tolerance, but as the benefits of such an adaptation appeared to be very doubtful and the dependence on additional clothes seemed an undesirable form of slavery, I decided that free ventilation was a sound investment in personal hygiene.

The main object of this regular exposure is to stimulate the thermogenic centre to a state of vigorous functional activity, so that when the individual is subjected to the inevitable changes of temperature such as occur on leaving the theatre or concert hall, the disciplined organism will adapt itself rapidly to the thermal transition even as it adapts itself to a cold bath without incurring a physiological débâcle. MacLeod [1] makes the interesting suggestion that the "congestion of the mucous membrane brought about by warm moist air does not probably depend on dilatation of arterioles, but rather on dilatation of capillaries, thus proving a stagnation of blood." If the circulation is sluggish and the thermogenic centre inefficient under certain conditions, the possibility of infection becomes almost a certitude. In my daily routine of exposing the body to the air for half an hour or so, respiration is accelerated especially in winter) and the nasal cavities are briskly ventilated. The tone of the mucous membrane is thus kept up and the occurrence of local congestion due to thermal variations is minimised, if not actually prevented. In this connexion many data are available showing the invigorating effects of open-air treatment and the rapid response to it. Lefèvre [2] states that a man who has been inured to it may sit for several hours in a cold wind without a reduction of body temperature.

Usually one finds that those who catch colds have faulty dietetic habits. The necessity of vitamins in the alimentary régime has been proved by many workers, and although neither their chemical composition nor metabolic rôle are satisfactorily known, experimental evidence supports the view that vitamins play a protean rôle, and that they cannot be synthesised by animals, which appear to require them constantly from fresh sources for perfect functional activity and also for resistance to bacterial infections and diseases generally. It is worthy of note, therefore, that in England people invariably eat vegetables and fruits cooked to a stagnant and supremely unappetising pulp. The water in which they are boiled is always thrown away, whereas on the continent it is carefully preserved and consumed, as mineral salts in solution are esteemed for their nutritive properties.

Food refinement and the chemical processes of sterilisation to ensure an artificial purity are not without serious dangers to health, and it is remarkable that all animals thrive on the coarsest and plainest foods. It is not amiss therefore to sound the warning "Memento te animal esse." An infinite range of food factors is destroyed by heating and manipulation and the body, being internally ill-treated and externally deprived of light and air stimuli, becomes incapable of achieving physiological equilibrium in the midst of the amenities of modern existence. A mere draught is then apparently sufficient to cause a procession of sore-throats and stuffy heads.

In conclusion, I will quote the words of the late Sir Clifford Allbutt, to illustrate a personal point of view put to the test:—

> "Concerning infections, I would add one more point to the precautionary methods of personal hygiene—namely, 'the toilet of the nose.' It has been a habit of mine, morning and evening, to rinse the nose well through the throat, ordinarily with water, but in times of epidemic, with a disinfectant solution. So far, I have never caught influenza or any other infection, although on more than one occasion I have received a full puff of breath from a case of pneumonic influenza."

Personally I often use a simplified method of prophylaxis by cleansing the nostrils with cotton-wool dipped in a 50 per cent. solution of iso-propyl alcohol, which Christianssen [3] found to produce complete disinfection in one minute in a series of interesting experiments on bacteria.

I am, Sir, yours faithfully,

MARK CLEMENT.

Department of Physiology, Middlesex Hospital, W.
Dec. 20th, 1927.

To the Editor of THE LANCET.

SIR,—Any treatment that will alleviate or cure this distressing state seems worth recording. Inoculations, given by themselves, are far from universal successes—for the simple reason that they are unable to cope with small deeply infected areas. It is my belief that in most of these cases there is a focus of infection that lights up the common cold and that this source of infection is almost invariably in the infected crypts of the tonsils, however harmless the tonsils may appear to the naked eye. Less commonly the source is purely nasal.

I have found the following method of treatment effective to an unusual degree. At weekly intervals I give the patient an inoculation of the three graduated doses of anticatarrhal vaccine as prepared by Parke, Davis and Co. With a Roger's fine crystal spray I get them to land half-a-dozen puffs from the spray on each tonsil morning and evening. A few puffs are put into each nostril also. The solution for the spray is a 25 per cent. solution of neoprotosil. The spray must be a very fine one, and very soon patients learn to become quite expert in its use, hitting the tonsils with a dexterity one would scarcely expect.

If the tonsils look red and the anterior pillars are injected, in two or three weeks these appearances clear up to a remarkable extent. The spraying is commenced with the first inoculation and kept up

[1] MacLeod: Physiology and Biochemistry in Modern Medicine, th edition, 1926.

[2] Lefèvre: Comptes Rendus, 1894, p. 604.

[3] Christianssen: Zeitschr. f. Physiol. Chem. 1918, cii., 275

regularly. Mothers very soon learn to do their children and children soon learn not to be afraid of the spray. I am convinced that the success of the method consists in the use of the inoculations plus the religious use of the spray at the same time. Inoculations are of little good if an untackled septic focus is lying in the throat ready at any minute to flare up; it is the neglect of treating this focus that brings about so much disappointment when vaccines are used alone. Enucleation, especially with children, is probably advisable in a large number of cases, but, for many reasons, one cannot always have this carried out with adults. With the above treatment I cannot recall a single case where, if the cure has not been completely successful, there has not been sufficient alleviation to satisfy the patient. Four other things I ask them to do—to sleep always with open windows, summer and winter, to bathe the chest and neck every morning with cold water, to take a diet where the vitamin element is balanced and a sufficiency of vitamin B made certain, and, finally, to learn how to breathe.—I am, Sir, yours faithfully,

A. GRAHAM-STEWART.

Ulster-place, Harley-street, N.W., Dec. 14th, 1927.

SACRO-ILIAC SUBLUXATION.

To the Editor of THE LANCET.

SIR,—An annotation on this subject in your issue of Dec. 17th suggests that international discussion might enlighten the discrepancies of surgical experience. You quote Sir Robert Jones and Dr. R. W. Lovett as outspoken sceptics, but in Vol. I. of the former's "Orthopædic Surgery of Injuries" we find a short chapter from the pen of Dr. F. C. Kidner, late consulting orthopædic surgeon, A.E.F., dealing with disturbances of the lumbar spine and pelvic girdle, and in this chapter the diagnosis and treatment of partial sacro-iliac dislocation is considered. Your annotation remarks on the apparent disproportion between the means of treatment adopted and the importance of the massive structures concerned, adding, "It is very hard to see how adhesive strapping, no matter how tightly applied to the skin, can exert any serious control over the sacro-iliac joint, even though it encircles the whole pelvis. Nor can we expect a spinal support or pelvic corset to be any more effective." Admittedly this would be so if we expected by such support to be able to relieve the weight-bearing function of the sacro-iliac joint. This, however, presupposes a downward displacement of the sacrum between the ilia, which few of those who have studied the problem would expect. The usual strain of this joint is a rotation strain, and it seems to me not irrational to suppose that a light support might be effective in relieving a strain of this kind. Even if the strain advances to subluxation, we should still not expect the rotation, forward or backward, of the ilium on the sacrum, to be recognised readily by ordinary examination, while the changes visible in a front-to-back X ray photograph would be negligible.

Is it not possible that the discrepancy in opinion arises from the fact that no detailed method of examination for this injury, or of this region, has been published, and that, therefore, the condition is frequently missed? There are countless patients who complain of pain in the back, sometimes traumatic, sometimes with no history of injury. How many surgeons (or physicians for that matter) are in a position to state confidently the cause of the pain? What, for instance, is meant by saying that a patient has chronic lumbago, or recurring sciatica? Can we take either diagnosis to mean anything more than that these patients have chronic pain in their back or leg? Then, too, what is traumatic lumbago? It is often held that this condition is due to a torn muscle. How often, when this condition is presupposed, is ecchymosis seen on the surface at any period of the trouble, and how often is the diagnosis made as the result of palpating the actual gap where the tear has taken place, or, failing this, by the only other possible method of diagnosis—namely, electrical stimulation of the muscles until pain is reproduced by causing the torn muscle to contract?

The following case came under my notice only last week. A nurse, while making a bed, suddenly felt something "give" in the small of her back; the pain was excruciating, and she was unable to stand upright and had to go to bed immediately. Under gas, a forward torsion strain was placed on the sacro-iliac joint, strapping applied, and the patient was immediately able not only to stand upright, but to walk across the room without pain. No manipulation could cure a torn muscle in five minutes, and I cannot conceive that the condition was hysterical or imaginary. If it was physical it can only be explained by assuming that the patient had sustained a locking of the sacro-iliac joint from a backward torsion strain, which was relieved by placing upon the joint a forward torsion strain. It is of course perfectly true, as your annotation implies, that the structures controlling this joint are immensely strong and firm. This, however, applies only to the structures which control the weight-bearing function of the joint. It does not apply to those which control the rotation, backwards and forwards, of the ilium on the sacrum.

I am, Sir, yours faithfully,

Park-crescent, London, W., Dec. 21st. JAMES MENNELL.

MERCUROCHROME INTRAVENOUSLY.

To the Editor of THE LANCET.

SIR,—I have had no trouble in several cases which have received doses of 5 mg. in 1 per cent. solution per kilo of patient's weight; but I have not repeated the administration oftener than twice a week. In a case of what is almost certainly infective endocarditis lenta or subacuta, a boy weighing at first about 60 lb. and now 50 lb., I have given three injections of 15 c.cm. of 1 per cent. solution, or rather more than 6 mg. per kilo, with no ill, and I regret to say no more beneficial, effect than a temporary reduction of temperature.

I am, Sir, yours faithfully,

JOSEPH O'CARROLL, M.D., F.R.C.P.I.

Dublin, Dec. 21st, 1927.

To the Editor of THE LANCET.

SIR,—I have had a small experience of mercurochrome which may be of some value. In my series of 29 cases it was not given for the treatment of acute infection but was used after operation with a view to preventing the onset of post-operative pneumonia. These cases were under my care during the latter end of 1926 and the early part of 1927. Young and Hill used up to 8 mg. per kg. of body-weight in a child and 6·8 mg. per kg. in an adult (Jour. Amer. Med. Assoc., March 1st, 1924, p. 669). My patients were all adults and I gave what I considered a safe dose for all patients, 20 c.cm. of a 1 per cent. solution. This was injected intravenously immediately following the operation and 10 c.cm. of a similar solution were given two days later. I treated 29 patients in this manner and in 10 of these there was a reaction, which occurred in the majority of cases after the second injection only. This suggests that the drug may be cumulative in action. The most common reaction consisted of a rigor with a rise of temperature to about 102° F. In two cases the reaction was slight, one patient complaining of a pain in the chest, and the other showing a small rise of temperature. In two the reaction was severe. One man had hæmaturia and passed blood in the stools, while another had a severe rigor, headache, cyanosis, and collapse.

From my experience I should advise the dosage and the increased dilution with repeated injections as advocated by L. S. Dudgeon.

I am, Sir, yours faithfully,

G. P. B. HUDDY, M.S., F.R.C.S.

The Hospital, Dudley-road, Birmingham,
Dec. 19th, 1927.

THE PRESENT POSITION OF THE VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—I am loth to disturb the Christmas peace by controversy, so I pass without the severe criticism it deserves Dr. Graham Little's offensive assumption that humanity and the spirit of service are only to be found in the voluntary hospitals; also his other amazing statement that the "highest pride" of the Poor-law hospital or infirmary is in affiliation to the voluntary one.

But what Dr. Little misses out is more important than what he puts in. It is not sufficiently realised that the voluntary hospitals only admit a limited number of strictly selected cases out of the much larger number needing hospital treatment; and that the discrimination is not made only on legitimate, clinical grounds but on financial, social, administrative, and even less creditable grounds. Innumerable cases are rejected whose need is nevertheless great, and who could and ought to be admitted if the voluntary system really met the public need. Secondly, a great deal of very bad treatment is done in out-patient and casualty departments with disastrous results. Some of these cases would be unbelievable if one had not seen them. The causes must be, I suppose, shortage of beds and lack of courage or of clinical judgment to tell the patients to get into hospital elsewhere at once. The question really is not "What do the voluntary hospitals do?" but "What do they leave undone or do badly?" It is unnecessary to praise their *best* work; it is probably the best in the world. As centres for teaching and research and in-patient treatment for the limited and strictly selected classes with which they deal, they stand very high. But what has to be looked at is whether they deal, and, if not, whether they can be reorganised so as to deal effectively with the great mass of patients. That A is treated with all the resources of modern skill is no use to B, who is excluded. And if the voluntary hospitals cannot cope with the mass, then other organisations must take up the work and will inevitably try to make themselves as efficient and up to date as they can. It is useless to complain of competition from State-aided or rate-aided or any other form of publicly provided hospital. These must have developed, even if they had been unwilling, because the cases are there needing treatment, and the voluntary system cannot, or at least at present does not, treat them.

I am, Sir, yours faithfully,

J. C. MUIR,
Medical Superintendent, Whipps Cross Hospital,
Dec. 24th, 1927. Leytonstone, E.

To the Editor of THE LANCET.

SIR,—Dr. Graham Little's defence of the voluntary hospital system will be, undoubtedly, pleasant reading for the managers of these institutions; but his conclusions are by no means convincing to many of us who have been for years working under this system. I would like to draw his attention to the problem of the isolated provincial hospitals which he has not considered so far in any detail.

It is my privilege to practise surgery in an industrial area with a population of upwards of 250,000, and there are in the entire district only 190 voluntary beds. It will be granted that this is a totally inadequate supply for such a large number of people; consequently, there is an increasing waiting list and a great number of complaints. The medical staff at the principal hospital is now rarely called upon to treat the really sick poor, the great majority of the patients dealt with are State-insured persons including, of course, the better-paid artisans. The others are a very various collection, including small tradesmen and their dependants, small farmers, salaried officials, and clerks who formerly never dreamt of availing themselves of the charity. In fact, if they had done so there would have been a great outcry from the profession as a whole on the old theme of hospital abuse.

This crowd of actual and prospective patients is gradually being increased by the activities of committees of what are now known as workmen's contributory schemes under which money is collected at most mills and workshops to the extent of 1*d.* or 2*d.* per week from the wages of the working people without any distinction as to the individual employee's financial position. The money is handed over to the hospital authorities quarterly on certain general conditions being granted—namely, that the workmen's committee is adequately represented on the board of management and the right of free maintenance and medical treatment for all subscribers. These schemes are growing fast and have undoubtedly saved many hospitals from serious financial trouble, but it is obvious the sick poor are no longer the real object for the service of the charity for they are surely and certainly being crowded out and must eventually seek more and more frequently admittance to the Poor-law infirmary, where curiously enough they are treated by a paid medical and surgical staff.

An inefficient system which cannot deal with more than 20 per cent. of the work it ought to do after years of effort would have been in ordinary circumstances scrapped or thoroughly revised long ago. There is a most urgent need for more hospital beds, and I feel certain that the quickest way to obtain these is to combine the services of the Poor-law and the general hospitals in the provincial areas, and let them be governed by a representative board of the two authorities. By this means considerable overlapping would be prevented and the cost of providing more hospital accommodation would be deferred for a time. This is not a drastic measure of reorganisation; but the chief difficulty will be the question of remuneration of the medical staff. Surely this could be met by percentage deductions as suggested by the British Medical Association from contributory schemes, and it seems to me only just that the National Health Insurance Committees and Insurance Societies, whose sick and injured fill the hospitals in ever increasing numbers, making more calls on the skill and time of the medical staffs, should also contribute their quota.

I have read Prof. Berry's interesting comments (THE LANCET, Dec. 24th, p. 1364) with great pleasure and heartily endorse his views on American and Continental hospitals. The genius of the Americans, especially for organising, has provided them even in the smaller cities with excellent hospitals which are run on a sound financial basis with facilities for modern treatment, investigation, research, and after-care which are not possible in the average provincial hospital at home chiefly on account of want of method and lack of funds. When I was in America the idea of the unprovided-for middle classes in England working out their own salvation by establishing hospitals at special centres on similar lines or on an insurance basis appealed to me as a feasible plan, and one that with the coöperation of the medical profession would meet with success, not to mention the great benefit it would confer on a section of the community who have in the past received insufficient consideration. I am, Sir, yours faithfully,

Burnley, Dec. 27th, 1927. JOHN H. WATSON.

AN OPERATION FOR THE ALLEVIATION OF DEAFNESS.

To the Editor of THE LANCET.

SIR,—Major Vincent Nesfield's article on this subject (THE LANCET, Dec. 24th, p. 1338) is most interesting to me. Had he been an aural, and not an ophthalmic, surgeon he might have known of the mastoid operation I introduced in 1906—of which thousands have been performed—on practically the same lines as the operation he now outlines. My operation, also, was outlined in your issue of August 11th, 1906; the ten cases there described (all that had then been performed) were exhibited

by me at a meeting of the British Laryngological, Rhinological, and Otological Association (the Royal Society of Medicine was not then in existence). Their perforated drums had healed and their hearing was so good (some absolutely perfect) that I received unanimous congratulations. The report of this meeting was published in your issue of Dec. 15th, 1906.

The great ear hospital at The Downs, Sutton, has, at this moment, 150 operations of this kind now in the wards. I was operating there two evenings ago. I hope when Major Nesfield exhibits his cases—as, of course, he will—that the results will justify his audience in also giving congratulations, for there are too many deaf people in this country.

I am, Sir, yours faithfully,

CHARLES J. HEATH, F.R.C.S. Eng.,
Consulting Aural Surgeon, The Downs Hospital; late Surgeon, Throat Hospital, Golden-square, W.

Dec. 26th, 1927.

To the Editor of THE LANCET.

SIR,—I have read with a degree of interest Mr. Nesfield's account of his operation for the alleviation of those cases of deafness which, he says, are caused by obstruction of the Eustachian tube or tubes. The first point that occurs to me in his writings, as indeed I anticipate it does to others interested in aural surgery, is whether Mr. Nesfield has previously to his operation made an attempt to open the closed Eustachian tubes with a bougie and catheter. If Mr. Nesfield has not on all occasions done so, I say his operation is an unjustifiable one; on the other hand, if he has done so, then his operation may possibly be justified. The fact must not be lost sight of that those long-standing cases of middle-ear deafness due to catarrh spreading up the tubes do often improve considerably after several treatments with the catheter and bougie together with suitable treatment of the nasal-pharyngeal catarrh.

I am, Sir, yours faithfully,

ARTHUR M. BARFORD,
Aural Surgeon, Royal West Sussex Hospital and Portsmouth and Southern Counties Eye and Ear Hospital.

Chichester, Sussex, Dec. 27th, 1927.

TOXÆMIAS OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—I would find it more easy to reply to the letter of Dr. J. N. Cruickshank, Dr. J. Hewitt, and Dr. K. L. Couper in your issue of Dec. 24th if I knew precisely the facts they definitely ascertained from the two lines of inquiry referred to in my letter. I can assure them that I had carefully noted the statements in their monograph as to (*a*) a full clinical examination having been made, (*b*) cases of infection of urinary tract having been included, and (*c*) their opinion as to the importance of protein in the dietary—an opinion which I fully share. They now tell us that the first statement necessarily implied a careful bacteriological examination of the urine, which failed to reveal any bacilluria, pyuria, or—but this is not specifically stated—bacteriuria. It would enable me to define my position in the matter more precisely if they will indicate clearly whether I am right in concluding that in a series of 200 consecutive cases of declared acute toxæmias in pregnancy the bacteriological examination of the urine gave a negative result, as presumably in the control cases, and if so, they will indicate the precise nature of the technique employed in the bacteriological examination. A further essential is a statement of the number and nature of the cells revealed by the careful examination of a centrifugal specimen of the urine, this being so frequently an indication of reaction in the urinary tract and the elimination of bacteria from the system by the kidney, this condition being not necessarily correctly described as a renal infection.

It is clear from their letter that we may not be at one in regard to definitions. Thus they state that they have not noted "any indication of intestinal putrefaction as we understand the term." It would enable me to define my position on this point if they will indicate what evidence, if any, can be obtained from the stools by the use of the unaided senses, indicating an excessive degree of putrefaction in the lower alimentary tract, and whether in the 200 cases investigated the odour of the intestinal contents as voided was not extremely objectionable.

The interesting points raised in their letter raise issues of far-reaching interest and importance in other fields of medicine. A few months ago I asked a gynæcologist of wide clinical experience what proportion of gynæcological cases commonly met with owed their origin, primarily and mainly, to a faulty state of the lower prima via, and he replied at once anything over 90 per cent. If this opinion is even approximately correct, it indicates the necessity of more attention being directed to the subject on the lines indicated in my letter. But this point can be more usefully elaborated when the authors have given us the additional information desired.

I am, Sir, yours faithfully,

Edinburgh, Dec. 27th, 1927 CHALMERS WATSON, M.D.

SPINNERS' CANCER.

To the Editor of THE LANCET.

SIR,—Dr. Robertson, in support of his view of the causation of this form of occupational cancer, has found evidence in the fact that in the United States spinners use belts to keep up their trousers rather than braces as in Lancashire, and that the trouble has not so far been reported from the States. When in the States early this year I set inquiries afoot and later discussed the subject with the American statistician, F. L. Hoffman. He now writes to me (dated Dec. 9th) as follows:—

"I have at last obtained definite information concerning mule spinners' cancer in the United States. As the result of a special analysis of all death certificates of scrotal cancer for the United States registration area for 1926, I have six records, three of which give the occupation as mule spinners and three as textile workers. The matter will be followed up later."

The bearing of this important information upon the causation of the disease will be clear to your readers. I am, Sir, yours faithfully,

EDGAR L. COLLIS.

Welsh National School of Medicine, Cardiff,
Dec. 24th, 1927.

ISOLATION OF MEASLES.

To the Editor of THE LANCET.

SIR,—It is perfectly safe for an *uncomplicated* case of measles to mix freely in society 14 days after the first appearance of the rash, convalescence being satisfactorily established. My reason for writing this letter is that I now find myself compelled to keep a patient at school over Christmas, because the medical man who attends her family asserts that it is unsafe for the child to return home till three weeks have elapsed from the first appearance of the rash. All the periods during which uncomplicated cases of the common exanthemata remain infectious are definitely known, and it is important that members of the medical profession should realise this fact. The data have been drawn up and printed by the Medical Officers of Schools Association, in consultation with epidemiologists of repute, and other leading consulting physicians, *and they have stood the test of time.* I say this without hesitation after more than 20 years' experience as medical officer of a public school. Since apparently there are still practitioners who are unacquainted with what should be by now a matter of common knowledge, it seems high time that the rules adopted by all our public schools should be circularised to the profession by some central authority such as the General Medical Council.

I am, Sir, yours faithfully,

F. J. CHILD, M.D. Camb.,
A Medical Officer of Winchester College and St. Swithun's Girls School, Winchester.

Dec. 26th, 1927.

TWO DISCLAIMERS.

To the Editor of THE LANCET.

SIR,—I find that my name has been used for advertisement by a well-known firm of woollen manufacturers. This advertisement is based on a health article which appeared in the daily press, part of which was appropriated without my knowledge or sanction. Apparently, all I can do is to notify this firm that I object to my name being used for advertisement purposes. This was done when the said advertisements first appeared. I would like my colleagues to know that I am guileless in this matter.

I am, Sir, yours faithfully,

ESTELLE COLE, L.R.C.P. & S. Edin., &c.

Harley-street, W., Dec. 27th, 1927.

To the Editor of THE LANCET.

SIR,—As medical officer I wish to disclaim responsibility for the extravagant claims appearing in the lay press on Dec. 21st and other dates *re* a case of encephalitis lethargica treated at the Burton-road Poor-law Institution, Lincoln. These reports were acquired by the press entirely from extra-medical sources. I am, Sir, yours faithfully,

Lincoln, Dec. 23rd, 1927. JAMES LYONS.

THE PLAGUE OF WRITING.

To the Editor of THE LANCET.

SIR,—I hear increasing complaints from my fellow practitioners of their time being so much occupied by the filling in of forms that the curing of their patients is seriously hampered; this increase in office work is due to several causes, the chief of which are the growing inroads into general practice made by central and local government departments and to a less extent by the enterprise of the daily press and others in organising insurance schemes against illness and accident. After an accident the patient's first thought is how much he can get from his insurance, and this necessitates one or more, usually several, elaborate reports being filled in by his medical attendant; if called upon to pay for these reports the patient is often most indignant. As regards national health insurance, in the beginning no complaint could be made of unnecessary clerical work being put upon the doctors; in fact it may be regarded as a triumph, at any rate for a Government department, that the essential certification had been reduced to one printed form; but of late a change has come over the scene. The increasing claims for additional benefits—e.g., ophthalmic, dental, surgical appliances, &c.—all require "extra" certificates which must be supplied free of charge; letters are required, quite rightly, by voluntary hospitals, before panel patients can be seen by their staffs; tuberculosis and other clinics ask for "a letter from the doctor," and now the Ministry of Health takes a hand and requires on Forms G.P. 17 and G.P. 36 detailed reports on all tuberculous patients on the practitioner's panel list.

There is also the vexed question of certificates covering absence from school through illness. The education authorities require such certificates, but will not pay for them—the parents cannot always afford to do so—the result is that some doctors refuse to sign any; others sign them for nothing, while yet others sign on payment of a fee, each course of action being open to grave objection. In addition to the above there are the signing of pensions, unemployment, and old-age certificates, for which, out of the long list of legally respectable people who may endorse them, it is usually the doctor who is the most easily accessible. A charge is seldom made for such services. Even in such simple matters as vaccination there is a great deal of unnecessary clerical work to be done. Before a public vaccinator can collect his fee for a vaccination performed at the home of the child he has to supply no less than 48 items of information on six different forms. It is, indeed, no wonder that the profession views any increase of clerical work with anxiety. I am, Sir, yours faithfully,

Dec. 15th, 1927. AN UNWILLING SCRIVENER.

Obituary.

ALEXANDER BLACKHALL-MORISON, M.D. EDIN., F.R.C.P. LOND.,

WE regret to announce the death of Dr. Blackhall-Morison, which occurred suddenly in London on Dec. 23rd, in the seventy-seventh year of his age.

Alexander Morison, who took later the additional name of Blackhall for family reasons, was the son of the late Alexander C. Morison, a medical officer of the H.E.I.C.S., and the grandson of Alexander Morison, the well-known Edinburgh physician and psychologist, in whose honour the Morison Lectures of the Royal College of Physicians of Edinburgh were founded. He received his medical education at the University of Edinburgh, where he graduated as M.B., C.M. in 1872, taking the M.D. degree with gold medal in 1878. In the previous year he had obtained the diploma of Member, and in 1889 was elected F.R.C.P. Edin. During this period he took out post-graduate courses in Berlin and Würzburg, so that when he entered upon general practice in the north of London he was highly equipped.

For upwards of 20 years he remained in general practice, during which time his careful writing and his communications to medical societies indicated his interest in cardiology. In 1892, having obtained the diploma of M.R.C.P. Lond., he was appointed to the staffs of the Royal Northern Hospital and of the Children's Hospital, Paddington Green, being already physician to the St. Marylebone General Dispensary. He continued his regular writing on such subjects as angina pectoris, heart failure, and the neuro-muscular factors in heart disease, and about this time joined the staff of THE LANCET, and was for some ten years a regular editorial contributor, while under his own name he published in our columns many original articles dealing with numerous cardiological points. Some of these articles, notably a series dealing with cardiac pain, were published in 1914 under the title Sensory and Motor Diseases of the Heart, and in this volume he set out very clearly his views on the nature of cardiac sensibility and motion, confessing himself an admirer of the revolution in cardiac therapeutics brought about by Mackenzie's work, while remaining the convinced disciple of the classic authorities—an attitude that brought him into frequent controversies. In 1897 he was appointed Morison Lecturer at the College of Physicians of Edinburgh, the circumstances being complimentary alike to his clinical work and to his pedigree, for a hundred years previously the first Morison Lecture on mental disease was delivered by his grandfather. He was elected F.R.C.P. Lond. in 1903.

His views, based on his own experience in general practice, of the alterations in the life and status of the practitioner that would follow upon the National Insurance Act were uncompromising; he took a strong line in opposition to panel practice, was elected joint president with Prof. William Russell of the National Medical Union, and on the nomination of the Union stood unsuccessfully for a seat upon the General Medical Council as a Direct Representative.

Blackhall-Morison was a man of deep convictions, whether in the details of therapeutics or the principles of practice, and a strong champion of the dignity of medicine.

THE LATE DR. J. EXLEY.—Dr. John Exley, of New Wortley, Leeds, who died on Dec. 8th, at the age of 62, had been in failing health for some time. He had intimate and family associations with Leeds, and received his professional education at the Yorkshire College. Qualifying as M.R.C.S. in 1887 he settled at once at New Wortley, and practised there until his death. He at one time held several public medical appointments, including those of medical officer in the Bramley Union and public vaccinator for the New Wortley District. He was also medical officer of the Leeds Prison at Armley for about 25 years, and was a justice of the peace, serving on the city council from 1920 to 1923. He leaves a widow, a married daughter, and a son, Dr. C. J. G. Exley, of Leeds.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

NURSING HOMES (REGISTRATION) BILL.

ON the order for the consideration of the Lords' amendments to the Nursing Homes (Registration)Bill, Mr. CHAMBERLAIN, Minister of Health, on Thursday, Dec. 22nd, moved to disagree with the amendment, which he said would place on the Minister the responsibility of the inspection of Christian Science houses. These houses were not nursing homes as that term was generally understood, and he held that the Minister of Health ought not to take responsibility for them.

The motion was agreed to.

HOUSE OF LORDS.

TUESDAY, DEC. 20TH.

THE Mental Deficiency Bill passed through Committee without amendment.

Nursing Homes (Registration) Bill.

Viscount GAGE, in moving the second reading of the Nursing Homes (Registration) Bill, said that it aimed at securing a better standard for nursing homes from the point of view of structure, management, accommodation, and staffing.

Viscount HALDANE said that while he had criticisms to offer in regard to certain provisions of the Bill he thought it was an extremely valuable measure and that it would be a misfortune if it failed to pass into law. Legislation was needed to raise the level of these nursing homes to a point which was compatible with safety.

Lord DAWSON said that there was by no means universal approval of the Bill. On the contrary, there were divers opinions in regard to it among the laity and the professional men who would have to carry out its provisions. The justification for the Bill was the report of a Committee of the House of Commons which disclosed serious abuses concerning certain nursing homes in various parts of the country. Anyone who had studied that report sufficiently must recognise that there were abuses which might justify action on the part of the Government. So far as the improvement of nursing homes from a professional point of view was concerned he was sceptical as to whether it was possible to improve them by any system of inspection. The real way to secure improvement was to set up proper institutions and buildings for the care of the sick. In so far as they did that the more inefficient nursing homes would cease to exist. The Bill gave powers of an extensive character, and those powers should be used with great discretion or they might lead to intolerable tyranny. He feared that there might arise a pettifogging type of inspector who would do more harm than good. One incidental effect of legislation of this kind would be that they would put the medical profession under the power of local authorities, and that would tend to promote the municipalisation of medicine in this country. He could understand people who were in favour of a State medical service voting for this Bill. He was in favour of setting up a health committee or authority which would correspond to the education committee or authority. That committee would deal with the health services and would bring the official and unofficial sections of the profession together. The case for the Bill was that it would prevent the abuses which were disclosed before the Select Committee.

Earl RUSSELL strongly criticised the clause dealing with Christian Science homes, and he protested against the action of the Minister of Health in suggesting that these homes should be called Christian Science Houses, thus advertising that dreadful religion.

The Marquess of SALISBURY, in reply, said that many of the points raised in the debate were committee points, and no pressure would be brought to bear on their lordships in regard to any amendments they might bring forward. In reply to Lord Dawson he pointed out that if they were to have control of any sort they must have inspection.

The Bill was read a second time.

WEDNESDAY, DEC. 21ST.

On the motion to go into Committee on the Nursing Homes (Registration) Bill,

Lord CHARNWOOD asked if it would not be possible for the Government to bring the Bill in afresh in the early days of next session.

Earl RUSSELL supported the suggestion.

Viscount HALDANE said he was most anxious to get nursing homes registered and he was not prepared to lay the Bill aside merely for minor considerations.

The Marquess of SALISBURY, Lord Privy Seal, said the case for protest against this method of legislation was overwhelming. It gave him great concern that year after year legislation was scamped because of the difficulties with which their lordships were confronted. If there was a very considerable feeling that the Bill should be postponed he would not resist it, but he would very much regret it.

The House then went into Committee on the Bill, the Earl of KINTORE in the chair.

On Clause 7 (Power of the Minister to exempt Christian Science Nursing Homes),

Viscount FALMOUTH moved to add a new subsection to provide that

> The Minister might at all reasonable times inspect any nursing home to which the clause applied, and might refuse exemption or withdraw exemption on the ground that the provisions of paragraphs (*a*), (*b*), or (*e*) of the proviso to subsection (3) of Clause 1 were not complied with.

Earl RUSSELL said there might be a case for granting exemption from the provisions of the Bill, and particularly the medical provisions, to a body which did not believe in medical treatment, but he could not see why it should be limited to one particular sect. The American sect founded by Mrs. Eddy was not the only one which held these peculiar opinions about medical attention. He therefore proposed to move later that Clause 7 be deleted and that the following clause be inserted in its place :—

> The Minister of Health may grant exemption from the operation of this Act in respect of any nursing home which he is satisfied is being carried on without medical or surgical treatment. Such exemption may be complete or partial, and shall remain in force for one year. No order of the Minister shall exempt a nursing home from the requirements of any bye-law made under Section 4 (1) (*b*)—which requires a report to be made of any death in a nursing home. An exemption granted under this section in respect of a nursing home may at any time be withdrawn by the Minister if it appears to him that the conditions have changed.

Viscount ASTOR said that unless some exemption were granted it would be impossible for Christian Science institutions to be maintained, and it was held in the House of Commons that that would be illogical and savour of persecution. As far as the Christian Science body were concerned, they would be ready to accept this amendment. They would welcome a form of inspection.

Viscount HALDANE said the question was whether they were to have this Bill or not. He was anxious that it should pass. He was as far away from Christian Science as Earl Russell could be, and did not believe in any of these exemptions.

Earl BEAUCHAMP supported Earl Russell's amendment.

Viscount GAGE, Lord in Waiting, speaking for the Ministry of Health, said that the Minister of Health felt that it would not be in accordance with the principles of religious tolerance to refuse this exemption clause. The Minister was prepared to make it perfectly clear that the whole object of listing these houses was to take away from the public any possibility of their imagining that these houses had any State supervision at all except for the irregularities for the information of which the Minister was relying on the Christian Science movement. If this clause were omitted Christian Science houses would be extinguished. The number of such houses must be very small, and it could not be contended that they would be likely to compete on any substantial scale with ordinary nursing homes.

The Marquess of SALISBURY, in reply, said that it would be impossible for the Government to accept an amendment which so radically altered the clause as did that of Earl Russell. That amendment would make it necessary for the Minister of Health to authorise any home which he was satisfied was being carried on without medical or surgical treatment. Such words were impossible. The Government had stretched a point to meet the conditions of the Christian Science sect, but Earl Russell's amendment was really like a condition in "Alice in Wonderland." He (Lord Salisbury) would not resist Lord Falmouth's amendment, but if the House of Commons refused to agree with it he could not pledge the Government to insist upon it.

Viscount FALMOUTH'S amendment was agreed to.

Earl RUSSELL then moved an amendment to substitute for Clause 7 a new clause on the terms which he had already stated to the House.

The amendment was rejected by 28 votes to 14 and the clause as previously amended was agreed to.

The remaining clauses of the Bill were agreed to and the Committee stage was concluded.

The Bill was then read the third time and passed.

THURSDAY, DEC. 22ND.

Viscount GAGE moved that the House do not insist upon their lordships' amendment to the Nursing Homes (Registration) Bill placing on the Minister of Health the responsibility of the inspection of Christian Science houses.

The motion was agreed to.

Prorogation and Royal Assent.

A Royal Commission was held for the purpose of giving the Royal Assent to a number of Acts passed during the session, including the following:—The Mental Deficiency Act; the Landlord and Tenant Act; the Nursing Homes (Registration) Act; the Medical and Dentists (Amendment) Act; and the Royal Edinburgh Hospital for Mental and Nervous Disorders Order Confirmation Act.

The Lord Chancellor read the King's Speech proroguing Parliament until Feb. 7th, 1928.

HOUSE OF COMMONS.

TUESDAY, DEC. 20TH.

Committee on Vaccination.

Mr. DAY asked the Minister of Health on how many occasions meetings had been held by the Committee on Vaccination which was appointed last year, and whether, in view of the recent outbreaks of small-pox, he could take steps to hasten the report.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is 30. As regards the second part I understand that the Committee are now considering their report.

Sick and Disablement Benefit.

Mr. ROBINSON asked the Minister of Health the number of persons aged 65 or over who would cease to be eligible for sick or disablement benefit after Jan. 2nd, 1928, and if he could furnish the numbers in receipt of sick benefit and disablement benefit separately.—Sir KINGSLEY WOOD replied: The number of insured persons who, by reason of having attained the pensionable age of 65, will cease to be entitled to sickness and disablement benefits under the National Health Insurance Acts on Jan. 2nd next is estimated at 355,000. It is impossible to say how many will be actually in receipt of either benefit on Jan. 2nd next, but the numbers are not likely to exceed 25 per cent. of the whole.

Nutritive Value of Pure Milk.

Lieut.-Colonel ACLAND-TROYTE asked the Minister of Health the result of analytical tests of the food value of one pennyworth of average pure new milk against one pennyworth of tinned machine-skimmed milk, and what was the percentage of fat in an ordinary sample of the latter.—Sir KINGSLEY WOOD replied: As regards the chief nutritive constituents of milk other than fat rather more of these can be obtained for one penny from condensed skimmed milk than from ordinary milk; as far as energy value is concerned considerably more is supplied by condensed skimmed milk owing largely to the sugar which it contains. The poorness in fat, however, which amounts to about 0·5 per cent., renders this milk unsuitable for infant-feeding.

Purification of River Pollutions.

Mr. OTHO NICHOLSON asked the President of the Board of Education whether the Special Committee of Scientific and Industrial Research, appointed to investigate the purification of river pollutions, had discovered a practical commercial process for the purification of the effluent from sugar-beet factories.—Lord E. PERCY replied: I understand that it is not yet possible to say whether the working-scale experiments which are in progress under the supervision of the Water Pollution Research Board will lead to a complete practical solution of the problem referred to by my hon. friend.

Children Under 14 in England and Wales.

Mr. GRIFFITHS asked the Minister of Health the total number of children under 14 in Great Britain and Northern Ireland.—Sir KINGSLEY WOOD replied: The estimated number of children in England and Wales under 14 years at mid-year 1926 is 9,366,000.

Health Insurance Statistics.

Mr. BENJAMIN SMITH asked the Minister of Health the number of persons insured under the Health Insurance Acts and the number of children under 14 years of such insured persons.—Mr. CHAMBERLAIN replied: The number of persons insured under the National Health Insurance Acts in Great Britain on Dec. 31st, 1926 (including persons over 70 years of age) was approximately 16,265,000, made up of 11,024,000 men and 5,241,000 women. I have no information as to the number of children under 14 years of insured persons.

Mr. BENJAMIN SMITH asked the Minister of Health the number of persons over 60 and over 65, respectively, who were insured under the Health Insurance Acts, and the numbers of such categories who were employed in the mining industry, the shipbuilding industry, and the iron and steel trades.—Mr. CHAMBERLAIN replied: At the date of the last valuation of approved societies the number of insured members of such societies in Great Britain who were 60 years of age or over, was as follows:—

Age.	Men.	Women.	Total.
60–64	437,000	95,000	532,000
65–69	283,000	54,000	337,000
70 and over ..	230,000	40,000	270,000
Total	950,000	189,000	1,139,000

Figures are not available for any later date and I have no information as to the distribution of the numbers between the several industries.

WEDNESDAY, DEC. 21ST.

Analyses under the Sale of Food and Drugs Acts.

Dr. VERNON DAVIES asked the Minister of Health if, in his next annual report of the Ministry of Health, he would draw attention to the advisability of seeing that analyses, under the Sale of Food and Drugs Acts, should primarily be for the purpose of detecting adulteration in the common articles of diet amongst the poor, and that, where past experience showed an adulteration of over 5 per cent. of the samples analysed of these articles of diet, it would be of advantage to the public health if a larger number of samples were analysed.—Sir KINGSLEY WOOD replied: My right hon. friend will consider whether any advice can usefully be given in this matter.

Unvaccinated Persons in Prisons.

Dr. VERNON DAVIES asked the Home Secretary what was the usual procedure with unvaccinated prisoners in regard to vaccination in normal times and during the presence of small-pox in the district or prison.—Sir WILLIAM JOYNSON-HICKS replied: In normal times no special steps are taken except as regards convicts sentenced to penal servitude, who, unless they present good vaccination marks, are vaccinated before removal to the convict prison. During an outbreak of small-pox in the area in which a prison, whether a local prison or a convict prison, is situated, or in areas from which prisoners are received, it is the practice to vaccinate all prisoners who have not been previously vaccinated within recent years.

THURSDAY, DEC. 22ND.

Adulteration of Milk.

Dr. VERNON DAVIES asked the Home Secretary what was the number of prosecutions in the county of Nottingham for the adulteration of milk during the years 1924, 1925, and 1926, with the penalties imposed.—Sir WILLIAM JOYNSON-HICKS replied: In the county the figures were, prosecutions, 16, 11, 13; fines, £20 19*s.* 6*d.*, £17 16*s.*, £22. If the city of Nottingham and the borough of Newark be included the following are the additional figures: prosecutions, 17, 4, 10; fines, £12, £15 8*s.*, £9 10*s.* The figures of fines do not include costs ordered to be paid in addition.

Contributions to Health Insurance Fund.

Mr. DAVID GRENFELL asked the Minister of Health the amount of contributions to the Health Insurance Fund for the years 1924, 1925, and 1926, with the number of insured persons receiving benefit in each year and the total number of weeks for which benefit had been paid.—Sir KINGSLEY WOOD replied: The amount of contributions paid into the National Health Insurance funds in Great Britain for the years specified was in round figures: 1924, £27,000,000; 1925, £28,000,000; 1926, £24,500,000. Exact particulars are not available as to the number of weeks for which sickness benefit and disablement benefit were paid, or as to the number of persons in receipt of benefit for any year, as no occasion has arisen for requiring approved societies to keep such statistics. It may, however, be estimated that the total number of weeks of sickness represented by the amounts paid as sickness and disablement benefit in each of the years specified was, on a rough approximation, 26,000,000 weeks in 1924; 28,000,000 weeks in 1925; 31,500,000 weeks in 1926.

SWEARING FOR A HOSPITAL.—The Royal Free Hospital has adopted an "anti-curse scheme" as a means of raising money. Its helpers have been provided with 2000 collecting boxes into which their friends will be invited to drop a coin every time they use a "profane oath." Each collector undertakes to obtain £5, and a prize of £100 is offered to the collector who obtains the largest sum.

MEDICINE AND THE LAW.

Insanity by Inference.

IN an overwhelming proportion of cases a person who is found "guilty" on a charge of murder makes an appeal to the Court of Criminal Appeal. The defence is often a plea of insanity, and it seldom succeeds. But the unexpected sometimes happens; on Dec. 12th, in the case of R. *v.* Lloyd the Court of Criminal Appeal substituted a verdict of "guilty but insane" for a verdict of "guilty." Lloyd had been tried at Durham Assizes before Mr. Justice Roche for murdering a policeman. His defence at the trial was insanity. His military medical records showed that in 1916 he was removed from duty in the field in France suffering from exposure, exhaustion, and shock, and after that date grave reports were made of his mental condition. In September, 1925, he was described as having a childish mentality, and as being a-social, unstable, and emotional. In 1926 he was said to be a congenital mental defective. The dead policeman had somehow upset him, and Lloyd threatened "to swing for him." Mrs. Lloyd said he had always been a good husband, but that last Christmas he had attacked her with a rolling-pin without any cause; he had seized his father-in-law by the throat and afterwards had cried when told what he had done: sometimes it had taken six or seven men to prevent his injuring himself and others. At the trial the learned judge gave the jury a rather broad hint that if they found the prisoner "guilty" and accompanied their verdict with a strong recommendation to mercy, the usual consequences would not follow. He explained that the result of the recommendation would be a reference from the Home Office to himself as presiding judge, and he intimated that, if consulted, he would give a favourable opinion. In effect, as the Lord Chief Justice observed at the hearing of the appeal, he possibly led the jury to think that it would be better for Lloyd if he were found "guilty" of murder, and thus he possibly dissuaded the jury from finding the accused to be insane. The Court of Criminal Appeal, Lord Hewart concluded, was satisfied that Lloyd was insane when he committed the act charged against him; it therefore substituted for the verdict of "guilty" a verdict of "guilty, but insane," it quashed the death sentence, and ordered that the prisoner be kept in custody as a criminal lunatic.

This paradoxical trial gave fresh proof of the judicial distrust of medical evidence recently expressed by Lord Hewart when discussing the danger of allowing uncontrollable impulse to be a defence. On Lloyd's appeal counsel for the Crown stated that no medical witness had been called to prove insanity in the court below. "The evidence of ordinary witnesses," thereupon remarked Mr. Justice Avory, "is often better than that of experts on those matters." Remarkable inferences might be drawn from the case. In the first place the man's insanity was so obvious that, after merely reading the documents and apparently without examining him, the Lord Chief Justice would have been prepared to certify him as a lunatic. In the second place, the judge and jury at trial, equipped with the same information, failed to detect unsoundness of mind in spite of the advantage of having merely "ordinary," and not expert, witnesses.

Dangerous Drugs Acts: Prosecution of Medical Practitioner.

Notification is made from time to time in the *London Gazette* when the Home Secretary withdraws a medical practitioner's authorisation to obtain drugs within the Dangerous Drugs Acts. A few days ago a practitioner was brought before a bench of magistrates upon two charges of attempting to obtain drugs after his authorisation had been withdrawn. It was stated that on Oct. 27th and 28th he had written to London asking for morphine. According to the brief report of the case in the *Times* he informed the justices that he did not recognise the law, and that the proceedings, if allowed to stand, meant that he was debarred from practice; no authority other than the General Medical Council could, he maintained, so debar him. The magistrates bound him over to appear on Jan. 3rd upon the condition that he made arrangements to enter a home. Thus, if he undertakes to undergo treatment, no more will be heard of the charge upon which the proceedings were taken.

Without more detailed knowledge of the facts it is difficult to offer any comment. The accused practitioner apparently stated to the bench that the medical profession did not want the Act, and that every registered chemist said the same. No doubt it is true that the medical profession was reluctant to be hampered by restrictions; but the arrangement under which he was charged was an honourable compromise between the Home Office and the profession; it represents an agreement reached by all concerned in the endeavour to control the supply of drugs to addicts. The case of doctors seeking to obtain drugs for their personal use received special attention, and to a considerable extent the undesirability of bringing doctors before police tribunals was sympathetically recognised.

Tyndall v. *Alcock.*

In the case of damages for negligence, which has been reported upon briefly in our columns (vide THE LANCET, Dec. 17th, p. 1318) the Council of the London and Counties Medical Protection Society Limited, has decided to appeal against the adverse verdict.

Medical News.

UNIVERSITY OF OXFORD.—At recent examinations the following candidates were successful:—

B.M., B.CH.

Medicine, Surgery, and Obstetrics.—L. W. H. Bertie, D. H. Brinton, H. A. Byworth, A. W. Cubitt, H. P. Gilding, R. E. Havard, A. P. Kingsley, J. C. Neely, Ripley Oddie, E. M. B. West, A. L. Wilkinson, and Olive H. Lister.

Forensic Medicine and Hygiene.—O. A. Beadle, A. R. Bowtell, A. W. Cubitt, H. P. Gilding, R. E. Havard, A. J. Leslie Spinks, M. G. Pearson, A. E. Porritt, L. T. Ride, E. E. Swaby, E. M. B. West, and Margaret A. L. Herbertson.

Pathology.—W. J. Cotton, H. R. J. Donald, J. M. Gibson, H. M. Harris, R. S. Harrison, A. J. M. Melly, F. G. Parker, and R. L. P. Peregrine.

UNIVERSITY OF CAMBRIDGE.—At a congregation on Dec. 19th the following degrees were conferred:—

M.D.—P. Lazarus-Barlow.

M.B. and B.Chir.—†G. F. Oakden, A. S. Hollins, and W. S. Grove. † By proxy.

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B. AND B.CHIR.

Part I., Surgery, Midwifery, and Gynæcology.—M. C. Andrews, W. R. Ashby, D. H. Belfrage, W. V. Boyle, W. Buckley, A. J. W. Chamings, A. D. Charters, A. G. Clogg, S. F. L. Dahne, J. T. Dunkerley, J. L. H. Easton, J. Foster, L. Foulds, J. L. Franklin, T. O. Garland, C. P. Giles, J. M. Graham, R. A. P. Gray, A. C. Hampson, L. T. Hilliard, E. M. Hoskin, W. H. Hubert, E. R. Keeble, M. Koettlitz, T. E. Lamech, J. M. Lees, W. J. Lloyd, R. A. McCance, D. J. MacMyn, W. N. Mascall, W. E. Mashiter, J. B. Murray, R. L. Osmaston, E. A. E. Palmer, V. E. Palmer, T. N. Parish, R. E. M. Pilcher, G. W. Pimblett, L. J. Rae, E. G. Recordon, W. H. G. Reed, F. A. Richards, R. W. N. Robins, G. Rocyn Jones, J. I. Sapwell, S. W. Savage, M. P. Shackle, L. Shillito, F. Smith, T. R. Smith, W. Smith, E. T. C. Spooner, B. Stewart, G. S. Storrs, I. C. C. Tchaperoff, D. R. Tweedie, W. E. Underwood, and F. H. Ward.

Part II., Physic, Pathology, and Pharmacology.—G. M. Addison, R. G. Apthorpe, J. R. Armstrong, G. H. Barendt, W. J. H. M. Beattie, H. Bell, B. Blaxill, G. J. O. Bridgeman, W. A. Briggs, J. W. D. Buttery, I. Caley, A. D. Charters, G. C. Dewes, G. A. Eason, T. I. Evans, J. Foster, H. Girling, A. R. Glover, S. J. P. Gray, M. J. Harker, E. T. James, G. K. Kirwan-Taylor, M. E. Lampard, L. C. Lancaster, R. M. B. MacKenna, W. S. Maclay, R. W. L. May, G. C. Milner, F. J. Milward, J. K. Monro, W. J. Moody, D. F. Oakley, R. L. Osmaston, C. L. Potts, P. E. Pym, J. B. W. Roberton, J. W. Shackle, M. R. Sinclair, J. F. Stent, T. R. Stevens, D. R. Tweedie, S. Tyagaraja, K. H. Uttley, J. R. S. Webb, E. V. E. Whidborne, W. J. Wilkin, D. F. Wilson, R. M. Windeyer, C. G. Windsor, and E. C. Wynne-Edwards.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful :—

PH.D. EXAMINATION.

Biochemistry.—John Knaggs, Imperial College—Royal College of Science.

D.SC. EXAMINATION.

Veterinary Pathology.—Francis C. Minett, private study.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Primary Examination for the Fellowship held from Dec. 6th to 17th, 169 candidates presented themselves, of whom 51 were approved and 118 were rejected. The following are the names and medical schools of the successful candidates :—

J. C. Anderson, M.B. St. And., F.R.C.S. Edin., St. Andrew's and Sheffield; M. Axford, M.B. Otago, Otago and Middlesex; L. H. Ball, M.B. Melb., Melbourne, Middlesex, and London; A. C. H. Bell, M.R.C.S., St. Bart.'s; Ilma B. S. Bingemann, St. Mary's; N. W. Bolton, M.B. Manch., M.R.C.S., Manchester; J. M. Buchanan, M.B. Melb., Melbourne and Middlesex; P. H. Charlton, Middlesex; A. M. Chaudhuri, M.B. Calcutta, Calcutta and St. Bart.'s; W. D. Coltart, St. Bart.'s; R. V. Cooke, M.B. Bristol, M.R.C.S., Bristol and Middlesex; S. G. Davidson, M.B. Aberd., Aberdeen and London; P. T. L. Day, Guy's; J. H. Doggart, M.B. Camb., M.R.C.S., St. Thomas's and London; G. C. Dorling, M.R.C.S., London; V. H. Ellis, M.R.C.S., St. George's and King's Coll.; W. R. Forster, M.S. Melb., Melbourne and Middlesex; Kathleen E. Gambrell, Lond. Sch. Medicine; A. D. Harper, M.B. Liverp., Liverpool; A. R. C. Higham, St. George's and King's Coll.; A. F. Hobbs, M.B. Adelaide, Adelaide and London; S. Howard, B.M. Oxf., Oxford, Adelaide, and London; T. G. I. James, M.B., F.R.C.S. Edin., Cardiff and St. Mary's; A. L. Johnston, M.B. Melb., Melbourne and Middlesex; J. A. Kerr, M.R.C.S., Birmingham and Middlesex; G. C. Knight, St. Bart.'s; J. C. Leedham-Green, B.A. Oxf., Oxford and London; D. L. Lewis, Cambridge; Muriel H. E. Long, King's Coll.; E. I. A. Macdonald, M.B. New Zealand, New Zealand and Middlesex; W. McKissock, King's Coll.; Moyra I. Macnaughton-Jones, Lond. Sch. Medicine; C. M. Marshall, M.B. New Zealand, New Zealand and Middlesex; I. D. Miller, M.B. Sydney, Sydney and Middlesex; D. K. Mulvany, King's Coll.; R. F. Phillips, M.R.C.S., St. Bart.'s; R. V. Powell, M.R.C.S., King's Coll. and St. Mary's; P. V. Reading, Guy's; E. Renbom, St. Bart.'s; R. F. Roberts, M.B. New Zealand, New Zealand and Middlesex; R. Rutherford, M.R.C.S., King's Coll.; C. D. Shapland, M.B. Lond., M.R.C.S., Univ. Coll.; C. K. Simpson, Guy's; F. E. Stabler, M.B. Durham, Durham; D. J. R. Steen, B.A. Camb., Cambridge and St. Thomas's; R. C. Tatham, M.R.C.S., Middlesex; H. Taylor and C. F. Watts, M.A. Camb., M.R.C.S., Cambridge and St. Bart.'s; R. A. K. Wiener, M.R.C.S., St. Thomas's and London; H. V. Wells, M.B. Lond., M.R.C.S., Charing Cross and St. Mary's; and F. G. Wood, M.B. Camb., M.R.C.S., St. Thomas's and London.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—K. D. C. Beckitt, Manchester and Charing Cross Hosp.; A. F. Briglmen, Edinburgh; L. J. Corbett, St. Mary's Hosp.; and H. S. Marks, Guy's Hosp.

Medicine.—K. E. Clarke, Charing Cross Hosp.; H. M. de Hartog, St. Mary's Hosp.; J. Miller, St. Bart.'s Hosp.; J. L. M. Wood, Sheffield.

Forensic Medicine.—L. J. Corbett and H. M. de Hartog, St. Mary's Hosp.; H. W. Maurer, Glasgow; and I. O. B. Shirley, St. Thomas's Hosp.

Midwifery.—S. A. Carr, Birmingham; G. L. McDermott, St. Bart.'s Hosp.; H. Tenenbaum, Nancy and London Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: A. F. Briglmen, S. A. Carr, H. M. de Hartog, J. Miller, and J. L. M. Wood.

UNIVERSITY OF LEEDS.—Dr. C. W. Vining has been appointed to the newly instituted chair in Diseases of Children; Dr. J. T. Ingram has been appointed Lecturer in Diseases of the Skin; and Prof. J. K. Jamieson, dean of the faculty of medicine, has been nominated representative of the University on the General Medical Council.—The University Council has approved a revised ordinance for the Doctorate of Medicine. The ordinance provides that the degree will be given by examination, but preserves the old principle of the thesis, which may be substituted for part of the examination, or for the whole if the thesis is of exceptional merit.

At a congregation held on Dec. 20th the following degrees were conferred :—

M.D.—Désirée M. B. Gross† and J. Science.

M.B., Ch.B.—F. Grundy,* W. Hyman,* F. V. Allen, J. Benson, J. Caplan, M. M. Day, Mildred I. Ealing, W. Levi, Mary Lightowler, W. Milligan, and J. H. Phillips.

†With distinction. *With second-class honours.

The William Hey gold medal was awarded to Mr. David William Currie.

UNIVERSITY OF MANCHESTER.—The newly instituted John Henry Agnew Fellowship in the Diseases of Children has been awarded to Dr. Marguerite F. Johnstone, who will go to the Orthopædic Institute in Bologna for research with Prof. Putti.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful :—

M.D.

R. W. Brookfield, Ethel Browning, Kathleen Edgecombe, and M. T. Morgan.

CH.M.

W. H. A. Dodd.

M.CH. (ORTH.).

L. O. Betts.

M.B. AND CH.B. (HON.).

Class II.—W. S. Creer and G. L. Roberts (distinction in Surgery), and S. L. Tunnicliffe (distinction in Medicine).

FINAL EXAMINATION FOR M.B. AND CH.B.

Part III.—A. B. Anderson, A. N. Cameron, D. E. Davies, Lilian W. Edwards, A. W. Green, Elsie A. Griffiths, I. Gurland, R. E. Jackson, T. Lotter, J. McWilliams, J. J. O'Donovan, G. W. Phillips (distinction in Medicine), J. W. Pickup, E. S. Smith, and E. F. Thompson.

Part II.—Ariel R. S. Deacon, H. F. Cohen, R. A. Furniss, J. E. Jones, Hilda M. C. McMahon-Garry, N. W. Roberts (distinction in Public Health), and Elizabeth B. Robson.

Part I.—W. W. Gerrard (distinction in Pathology), I. Kossew, and I. Lipschitz.

DIPLOMA IN TROPICAL MEDICINE.

H. S. Bawa, R. R. Evans, F. A. Khan, M. M. Khan, P. N. H. Labuschagne, W. J. Laird, B. F. Lewin, A. I. Meek, H. C. Mehta, M. V. Menon, H. V. R. Miller, S. N. Mokand, F. Murgatroyd, Pauline V. Murray, P. L. Nirula, D. O. Peters, J. H. Pottinger, G. V. S. Rodriguez, H. Singh, S. D. Sturton, and S. A. Wilkinson.

DIPLOMA IN TROPICAL HYGIENE.

P. N. H. Labuschagne.

UNIVERSITY OF BIRMINGHAM.—The following degrees were conferred on Dec. 16th :—

M.D.—*L. C. Hill, *A. V. Neale, J. A. Scott, and W. Summers.

M.B. and Ch.B.—Mary E. A. Allen, C. C. Cookson, L. H. Crossley, J. F. Duesbury, A. M. Ghaith, R. D'A. Gifford, D. V. Hague, S. K. Mansor, W. H. Shilvock, F. Smith, and R. W. W. Watson.

* With honours.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College on Dec. 16th Mr. Alexander Miles, the President, in the chair, the 49 successful candidates out of 94 entered, who passed the requisite examinations between Sept. 26th and Oct. 5th, were admitted Fellows :—

Harold H. Barnett, Israel Blain, Paul D. Braddon, Clifford V. Braimbridge, John W. D. Buttery, Walter J. W. Close, Peter Connan, Carlton E. Cross, James T. Danis, Bessie P. Darling, Bernard V. Dunn, James T. R. Edwards, Herbert G. Furnell, Eric G. Gorstenberg, Richard E. Gibson, Ewen G. M. Gilchrist, James C. Gillies, William C. Gissane, William R. D. Griffiths, Eric W. Gutteridge, William G. Hazelton, William A. Hervey, Stuart W. Houston, Leonard W. Johnston, Mary Keith-Thompson, Gordon B. King, Frederick A. Lamb, George E. J. Lannin, George Lowe, Derrick J. Martin, Ralph Morton, Elayedath A. Menon, Kunnankalathmadhathil Rama Menon, Joseph MacGowan, Archibald A. MacKelvie, Donald C. MacRae, Shena MacVicar, Daniel J. P. O'Meara, Nadkorni Mangesh Rao, Samuel I. H. Reid, Cecil C. Ross, Kevin Bush, Albert E. Sawday, Hector M. Simpson, Harbhajan Singh, Cyril M. Smithies, Thomas W. Stephens, Norman Waddle, and Ai Sung Wong.

UNIVERSITY OF DURHAM.—At the Convocation held on Dec. 23rd the following degrees and diplomas were conferred :—

M.D.—C. N. Atlee.

M.B., B.S.—W. R. S. Good, Gerald Holmes, T. F. Jarman, W. A. Kirkpatrick, Eleanor Patterson, and V. B. Purvis.

B.Hy. and D.P.H.—E. L. Ewan, Iris M. Pratt, and W. S. Walton.

METROPOLITAN HOSPITAL SUNDAY FUND.—At the annual meeting of this fund at the Mansion House it was stated that this year's total of £86,935 was £114 less than last year's.

TUBERCULOSIS SOCIETY.—A meeting of this society will be held at 8 P.M. on Friday, Jan. 20th, at the house of the Royal Society of Medicine, 1, Wimpole-street, W. A discussion on the Work and Aims of Tuberculosis Care Committee and Kindred Agencies will be opened by Dr. G. Jessel, Dr. A. P. Ford, and Miss Lewis.

PEOPLE'S LEAGUE OF HEALTH.—A series of eight lectures on the Mind and What We Ought to Know About It is to be given by Dr. H. Crichton-Miller, Dr. E. D. Macnamara, Dr. R. D. Gillespie, Dr. Thomas Beaton, Sir Robert Armstrong-Jones, Dr. Edward Mapother, Dr. W. A. Potts, and Dr. A. F. Tredgold, beginning on Jan. 25th. A series of lectures on Nutrition in Health and Disease will start on Feb. 17th, the lecturers including Dr. Leonard Hill, Dr. Harry Campbell, Dr. L. J. Harris, Prof. V. H. Mottram, Prof. Winifred Cullis, and Dr. Eric Holmes. Particulars may be had from Miss Olga Nethersole at 12, Stratford-place, W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY, Jan. 4th.—5 P.M., HISTORY OF MEDICINE. Papers: Miss Tildesley: (1) A Case of Post-mortem Trepanning about Mid-Sixteenth Century; (2) Extensive Healed Skull Wounds, probably of Roman-British or Anglo-Saxon Period. A number of interesting anthropological specimens will be exhibited by permission from the Museum of the Royal College of Surgeons of England. Members are cordially invited to bring any specimens they may have in their possession which they think would be of interest. 8.30 P.M., SURGERY. Paper: Mr. Zachary Cope: Criticism of Current Views of Shock and Collapse.

THURSDAY.—8.15 P.M., TROPICAL DISEASES. Laboratory Meeting at the London School of Hygiene and Tropical Medicine, 23, Endsleigh-gardens, Euston-road, W.C. 1. Illustrations will be given of the techniques discussed at the last meeting of the Section.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, W.

MONDAY, Jan. 2nd.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Dr. Trevor Davies: Gynæcological Department.

TUESDAY.—2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients. 4.30 P.M, Dr. Carmichael Low: Malaria and Blackwater Fever (lecture).

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. MacDonald: Genito-urinary Department. 2 P.M., Mr. Bishop Harman: Eye Department.

FRIDAY.—10 A.M., Dr. Pritchard: Special Medical Treatment Clinic. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—10 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Owen: Medical Diseases of Children.

Medical and Surgical Out-patients, Operations, Special Departments, daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Jan. 2nd.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Jan 3rd.—3.15 P.M., Mr. C. L. Gimblett: External Eye Disease.

Appointments.

COCHRANE, H. L., M.B., B.Ch. Belf., has been appointed House Surgeon, Royal Infirmary, Oldham.

HOLDEN, O. M., M.D. Birm., D.P.H., Medical Officer of Health for Croydon.

MILLER, J.W., M.B., Ch.B. Glasg., D.P.H., Medical Officer of Health, Lewisham Borough Council.

Manchester Northern Hospital for Women and Children: SUTHERLAND, D. MCKAY, M.D. Manch., Honorary Assistant Surgeon for Children; DYSON, MARGARET, M.B., Ch.B. Manch., Senior House Surgeon; EDWARDS, MURIEL M., Junior House Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: CALDWELL, J.S., L.R.C.P., L.R.C.S. Edin. (Aberlour District of the County of Banff); SEAGER, F. R., L.R.C.P., L.R.C.S. Edin. (Wolston District of the County of Warwick); and MORRICE, A. M., M.B., Ch.B. Aberd. (Southampton District of the County of Southampton).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Hospital for Sick Children.—Lady Supt.

Accrington, Victoria Hospital.—H.S. £150.

Barry Urban District Council, Accident and Surgical Hospital.—H.S. At rate of £200.

Bath, Royal United Hospital.—H.S. At rate of £120.

Belfast, Joint Nursing and Midwives' Council, Northern Ireland.—Examiners of Midwives.

Birmingham Pensions Hospitals Committee.—Jun. Surg. O. £300.

Bristol General Hopsital.—Hon. Med. Registrar.

Bristol, Ham Green Fever Hospital and Sanatorium.—Asst. Res. M.O. £300.

Canterbury, Kent and Canterbury Hospital.—Third Res. M.O. At rate of £125.

Central London Ophthalmic Hospital, Judd-street, W.C.—Two Out-patient Officers. Each at rate of £150.

Derby, Derbyshire Royal Infirmary.—Hon. Gynæcologist.

Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £200.

Freemasons' Hospital and Nursing Home, 237, Fulham-road, S.W.—Res. M.O. At rate of £250.

Guildford Union.—Res. Asst. M.O. £150.

Hospital for Consumption and Diseases of Chest, Brompton, S.W.—H.P. £50 for six months.

Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—Hon. Asst. P.

Hull Royal Infirmary.—Second H.S. At rate of £150.

Leeds Public Dispensary.—Jun. Res. M.O. £150.

Lincoln, The Lawn.—Med. Supt. £700.

London School of Hygiene and Tropical Medicine, University Chair of Public Health.—£1300.

Manchester, Ancoats Hospital.—H.S. £100.

Manchester, St. Mary's Hospitals.—Three H.S.'s. Each at rate of £50.

Margate, Royal Sea Bathing Hospital for Surgical Tuberculosis.—Two H.S.'s. Each at rate of £200.

Mount Vernon Hospital for Diseases of Chest, Northwood, Middlesex.—Asst. Res. M.O. At rate of £250.

Northampton, Creaton Sanatorium.—Med. Supt. £550.

Oldham County Borough.—Res. Asst. M.O.H. £450.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Anæsthetist.

Queen Mary's Hospital for the East End, E.—Anæsthetist. 25 guineas.

Royal Army Medical Corps.—Limited number of Commissions.

Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Clin. Assts.

Royal London Ophthalmic Hospital, City-road, E.C.—Two Out-patient Officers. Each £100.

St. Mark's Hospital for Cancer, &c., City-road, E.C.—H.S. At rate of £75.

St. Pancras Dispensary, 39, Oakley-square, W.C.—Res. M.O. £185.

Shanghai Municipal Council, Public Health Dept.—Asst. Pathologist. 600 Taels per mensem.

Southport General Infirmary.—Hon. Radiologist.

Warrington Infirmary and Dispensary.—Jun. H.S. £175.

Watford, Peace Memorial Hospital.—Res. M.O. At rate of £150.

Weston-super-Mare Hospital.—Res. M.O. £130.

Wolverhampton and Staffordshire Hospital.—H.S. At rate of £150.

Wrexham and East Derbyshire War Memorial Hospital.—Hon. Asst. P. and S.

A vacancy for a Surgeon as a Medical Referee under the Workmen's Compensation Act for Circuit 54, Bristol, Wells, &c., is announced. Applications should reach the Private Secretary, Home Office, Whitehall, S.W., not later than Jan. 21st.

Births, Marriages, and Deaths.

BIRTHS.

LANE.—On Dec. 22nd, at 9, Lancaster-road, Swiss Cottage, to Margherita, wife of Dr. C. Rickword Lane—a daughter.

NEWTON.—On Dec. 20th, the wife of Dr. F. L. Newton, of Malvern, of a daughter.

RUSHWORTH.—On Dec. 12th, at Orchard Corner, Walton-on-Thames, the wife of Arthur N. Rushworth, M.R.C.S., L.R.C.P., of a son.

SMART.—On Dec. 21st, at Seaton, Devon, the wife of A. H. J. Smart, M.B., of a daughter.

DEATHS.

BLACKHALL-MORISON.—On Dec. 23rd, suddenly, at Upper Berkeley-street, W., Alexander Blackhall-Morison, M.D., F.R.C.P. Edin. and Lond.

FALLA.—On Dec. 16th, at Adelaide Lodge, Jersey, Walter Falla, M.R.C.S., L.R.C.P. Lond., aged 71.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INSTITUTE OF PSYCHO-ANALYSIS.—Dr. John Rickman will give a course of lectures for medical practitioners and students, under the auspices of this institute, at the London Clinic of Psycho-analysis, 39, Gloucester-place, W., on Friday evenings at 8 P.M., from Jan. 27th to March 2nd. Particulars may be found in our advertisement columns.

GUY'S HOSPITAL.—An appeal is being made for help to reduce last year's deficit of £24,000 upon an expenditure of £170,000. It is explained that, contrary to the popular impression, Guy's is not a rich institution, its endowed income being only £65,000. Over 30 per cent. of its patients come from outside the London area, and a large proportion of the metropolitan patients come from districts other than its own.

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN PALESTINE AND TRANS-JORDANIA.

THE report made by H.M. Government to the Council of the League of Nations on the administration of Palestine and Trans-Jordan for the year 1926 has been issued from the Colonial Office. In regard to Palestine it is stated that the general health of the community was satisfactory, apart from the heavy incidence of enteric and dysentery in certain populous settlements, where conditions of sanitation and housing were bad, or where a pure water supply was inadequate and unsafe sources were used. There were 1400 cases of enteric, with 110 deaths, and 1732 of dysentery, with 37 deaths. During this epidemic certain of the voluntary hospitals rendered valuable service, notably the Kupat Holim Hospital at Ain Harod. The general inoculation of Jewish settlers in the Valley of Jezreel curtailed the epidemic in that highly infected area. In Tel-Aviv about 20,000 double doses were administered. Measures are being taken in coöperation with municipalities and Jewish organisations to remedy the insufficiency of conservancy and sanitary arrangements in the smaller settlements and the overcrowding in towns, also to provide additional sanitary officers and to augment the hospital accommodation for fever cases. There has been no serious outbreak of any other infectious disease, and no case of cholera or small-pox. One case of plague was landed at Haifa in November, and discharged from hospital cured in the following month. An intensive campaign of revaccination against small-pox was carried out in the spring, when 170,881 vaccinations were performed.

The estimated population at July 1st, 1926, was 761,896 (excluding Bedouin). Births during the year numbered 40,721, or 53·45 per 1000 population; and deaths 18,623, or 24·44 per 1000. Infantile mortality was 6644 = 163·15 per 1000 births. The syphilis clinic at Hebron has proved of considerable benefit. A second clinic is being opened for Bedouin in the Beersheba district. Out-patient dispensary treatment is provided for leprosy cases which cannot be admitted to the Moravian Mission Leper Home. There are not more than 50 lepers in the country; 25 are accommodated in the Home, which at present will only accept unmarried inmates.

The pilgrim route by the Hejaz Railway to Ma'an, and thence by land or sea from Akaba, was protected by the closure of Akaba port for pilgrim ships and the establishment at Ma'an by the Trans-Jordan Government of a temporary lazaret, laboratory, and epidemic hospital. Over 25,000 routine examinations were carried out in the central laboratories: the bacteriological subsection produced 60,465 c.cm. of carbolised antirabic vaccine, 442,750 doses of small-pox lymph, 107,000 c.cm. of antityphoid-paratyphoid vaccine, and 5140 c.cm. of anticholera vaccine. The routine tests of efficacy in children of the small-pox lymph gave an index of successful vaccination of 99·4 per cent. out of 1298 vaccinations performed and observed. The chemical subsection undertook investigations in connexion with sewage disposal, arsenical poisoning, and the adulteration of indigenous oils. Much progress was made in the towns and hill villages in the mosquito-proofing of rain-water cisterns. In the plains, extensive reclamation works were undertaken by Jewish organisations at Kabbara and in the Kishon area. Government medical officers and the Malaria Research Unit carried out a large number of small drainage schemes in conjunction with villagers and Jewish settlers. The Malaria Survey Section surveyed the Wadi Musrara and the Wadi Rubin swamps, where the Supreme Moslem Council is about to drain its lands. As a result of these measures and the low rainfall during the winter the amount of malaria in the country further decreased and there were no extensive epidemics of the disease.

The last years have seen a remarkable growth of infant welfare work in Palestine. The Hadassah organisation now maintains or supervises some 15 centres in Jerusalem, Tel-Aviv, Haifa, Tiberias, and in Jewish settlements. Local committees have started the same activities in Nablus, Haifa, Ramleh, Acre, and Bethlehem, and are securing the interest of the local populations. The British superintendents of midwifery at Jerusalem and Nablus will train nurses in the work. The Government ophthalmic clinics at Gaza, Ramleh, Beersheba, Nablus, Tulkarem, and Acre, with nursing staff trained and provided by the Ophthalmic Hospital of the Order of St. John at Jerusalem, have now become established. The high standard of technical proficiency attained is attributable to the skilled supervision of the surgeons of the Order. A Dentists Ordinance was promulgated in September, and regulates the practice of dentistry by qualified dentists and certain unqualified practitioners of long standing in the country. 105 import certificates were granted for the importation of dangerous drugs for legitimate medical or scientific use, as follows: opium, 15,489 g.; morphine, 1490 g.; heroin, 259 g.; pantopon, 57 g.; cocaine, 8515 g.

A considerable decline in the volume of immigration, and a simultaneous increase in the number of emigrants, were outstanding features of the year. Apart from the local trade depression, the financial disturbance in the countries of Central Europe, and particularly that in Poland (the provenance of 50 per cent. of the immigrants), impoverished prospective immigrants, and thus curtailed materially the flow of capital into Palestine. The number of immigrants during the year was 13,910 (6,276 men, 4864 women, and 2770 children), of whom 13,081 were Jews. The figures present a striking contrast to those for the year 1925, when 34,641 immigrants entered the country, of whom 33,801 were of Jewish race. The total number of emigrants during the year was 9429, of whom 7735 had settled in the country only since 1920. Three-quarters of the emigrants were working men and women. The volume of unemployment increased constantly throughout the year from 3000 at the end of 1925 to 8000 at the end of 1926. 52,301 travellers and 22,802 returning residents entered Palestine during the year, and 50,576 travellers and 24,695 residents left temporarily; in 1925, 87,666 travellers and returning residents entered Palestine, and 76,682 left. Tourist traffic showed an appreciable increase above that of the previous year. Numerous conducted parties visited the country.

CHRISTMAS POEMS.

Dr. Herbert A. Smith, 1, Denbigh-road, West Ealing, has sent us a collection of verses which he has prepared as a Christmas card. The devotional spirit is unmistakable, and the attempt in the verses to bring the old doctrines of revelation into line with modern thought is praiseworthy. The verses are illustrated with pen-and-ink drawings, and a limited number of copies, entitled Studies in Song, are available at 5*s.* from the author.

THE MIDWIFE'S PRONOUNCING DICTIONARY AND ENCYCLOPÆDIA.

THE pocket dictionary and encyclopædia of obstetrical and gynæcological terms, originally edited by Dr. Henry Robinson, has now been revised and reissued by Dr. J. K. Watson. It is in effect a compendium of information for the practising midwife, arranged in alphabetical form. The definitions are crisp and couched in terms which can readily be understood, and the text is interspersed with illustrative diagrams. At the end of the alphabetical section is a comparison of Centigrade and Fahrenheit thermometric scales, a transcript of the charts in use at Queen Charlotte's Hospital, and the rules of the Central Midwives Board. The book, which is published by the Scientific Press (Faber and Gwyer, Ltd., 24, Russell-square, London, W.C.), costs 3*s.*

HEALTH VISITING AS A PROFESSION.

THE writer of an attractive little book[1] on Health Visiting explains that her aims are fourfold: To explain to the general public the work of the health visitor; to give the student of health visiting an idea of what her future work will involve; to help her in her studies; and to act as her guide until she shall have had sufficient experience to face her problems without help. In these aims the author has succeeded admirably. Health visiting is indeed a new profession, and the qualifications and training required, the actual duties and the salaries to be demanded have not yet been standardised. A book written with knowledge of the present condition and outlook should therefore be welcomed by students and others who desire an insight into the life of a health visitor. After giving some general information Miss Armstrong devotes four chapters to the health visitor's work in connexion with home visiting centres and clinics, clerical work and antenatal care. Nearly all the rest of the book is given up to questions of feeding, clothing, care, and management in infancy and childhood, and common ailments, an appendix giving useful synopses of talks for mothers. Practically all the advice is sound and on common-sense lines; the chapter on common ailments is least successful. For example, thrush is due to a fungus and not to a germ; nettle-rash should not be distinguished from urticaria, for which it is a synonym; and albumin water should emphatically *not* be given indiscriminately in all forms of diarrhœa, since in infections by proteolytic organisms it is the worst possible measure. This section should be carefully revised, for the rest of the book makes good reading.

THE SAVANT IN THE FLOWER GARDEN.

Dr. F. Dawtrey Drewitt, author of "The Romance of the Apothecaries Garden at Chelsea," has published another little volume entitled "Latin Names of Common Plants: Their Pronunciation and History," for which gardeners and all who love their gardens will be grateful to him. He gives the origin of the names of garden flowers and shrubs, with the correct pronunciation of Latin names and much other information. The matter is scholarly, the writing easy, and (mirabile dictu) there is an excellent index. The book, which is well arranged and beautifully printed, would make an acceptable present to gardening friends. It is published by Messrs. H. F. and G. Witherby (326, High Holborn, London, W.C.) at 3s. 6d.

A SIMPLIFIED OPHTHALMOSCOPE.

Mr. E. Leslie Farquharson, a medical student in the University of Edinburgh, has devised a simple and cheap ophthalmoscope which takes the form of a small attachment, fitting over the end of an "Ever Ready" pocket torch ("fountain pen" type). It consists of a hood with a small sight aperture at the back, containing a slotted stainless steel mirror set at an angle of 45°. This hood is mounted on the upper end of a conical tube, the base of which is joined to a cylinder, as shown in the illustrations. At the junction of the cone and cylinder a lens of suitable focal length is fitted. The cylinder slides up and down over a collar fitted to the barrel of the torch, allowing an accurate focusing adjustment. A slot is cut away in the roof of the hood to prevent any reflection therefrom.

Attachment alone.

Complete with torch.

The special advantages claimed for this instrument are its simplicity, small size, and low cost. It is only about 2½ inches long, and can be conveniently carried in the pocket, either attached to the torch or separately. As it is not fitted with a system of lenses, it cannot, of course, be used for investigating errors of refraction, or for examining the anterior parts of the eye; but where the eyes of the patient and observer are both of approximately normal focus it will give a good view of the fundus.

The instrument has been devised primarily for the benefit of medical students, who are advised to familiarise themselves with the routine examination of the fundus oculi, but to whom the cost of the electrical ophthalmoscopes at present on the market is sometimes prohibitive. It is also suggested that it may prove useful to practitioners who feel the need of some simple yet satisfactory instrument for examining the ocular fundus. It is obtainable from the Medical Supply Association, price 9s.

THE SERUM TREATMENT OF ACUTE POLIOMYELITIS.

IN a paper on this disease given before the Medical Society of London last February,[1] Dr. F. M. R. Walshe referred to serotherapy as a method which had given promising results in the pre-paralytic stage, but which was neither reliable in itself nor adequate to the demands of a severe epidemic, because only human serum, and not much of that, was available.

At a recent congress of French-speaking pædiatrists held at Lausanne,[2] the principal speaker (Dr. Etienne, of Nancy) recalled the work of Netter, who had succeeded in curing patients, even after paralysis had set in, as long ago as 1910. Netter's experiments, he said, had shown definitely that the serum was efficacious both in monkeys and men; the intrathecal method was the most efficient, and the serum best tolerated was human serum, although good results had been obtained from horse serum, which, however, was more liable to irritate the meninges. The serum of Pettit, which is prepared in a manner similar to that used against rabies, gives the best results, according to several of the speakers at this session, and Dr. Etienne also strongly recommended that of the Pasteur Institute. The treatment is, he says, specific to a high degree, so much so as to afford a means of differential diagnosis from other varieties of myelitis. After citing a number of successful, and sometimes remarkable, results, he gave as his opinion that one of the chief reasons why its use had not become universal was that clinicians did not give large enough doses. He recommended the intrathecal method to begin with in severe cases, always with the precaution of observing the patient for meningeal symptoms, and laid down 350 c.cm. as the minimum total dose; 80 to 100 c.cm. should be given the first day, and 40 to 80 on every successive day until obvious improvement takes place. The serum should be allowed 12 hours to act. Although the earlier the treatment the better are the patient's chances, it is never too late, and in the forms of slower development even 60 days is not a hopelessly long delay. The examples he gave included nine complete cures out of 11, the two being a diabetic in whom the disease was arrested in spite of the bad general condition, and a patient who had been left untreated for seven weeks.

ULTRA-VIOLET EQUIPMENT.

THE current catalogue and price list of the Hewittic Electric Co., Ltd., of Walton-on-Thames, Surrey, illustrates the latest models of mercury-vapour lamp, powerful lamps suitable for large scale treatment in hospitals or clinics, as well as smaller lamps for use in the consulting-room. The tendency at present is for ultra-violet therapy to become part of the general practitioner's equipment and the light stand or light suspension "Ulviarc" lamp seems well suited to this purpose. The Hewittic Company were pioneers of mercury lamp construction in this country, and their all-British quartz lamps compare favourably both in workmanship and cost with foreign products.

A recent improvement in the design of Kromayer lamps has been introduced by the British Hanovia Co., of Slough, Bucks, making the lamp independent of the main water-supply, since it carries its own reservoir in the base of the stand. The water is circulated by means of a pump, and by an ingenious arrangement of the switch it is impossible to strike the arc until the water circulation around the lamp is established. Two of the practical disadvantages of the lamp—the inconvenience of trailing water-pipes and the danger of turning on the lamp before filling the water-jacket—are thus eliminated.

COFFEE.

IN spite of animal experiments and human experience the proper place of coffee in diet, and of caffeine in therapeutics, remains to a certain extent doubtful. This, at any rate, is the opinion of Dr. R. R. Irvin, of Pittsburgh, who has lately summarised the evidence on what he terms the "hygienic aspects of coffee."[1] As a beverage, he points out, it has certainly stood the test of time, for it was used in Arabia in the ninth century, and in Persia even earlier. Reaching Europe in the latter part of the sixteenth century, it at once became popular owing to its stimulant properties, pleasant taste, and fragrant aroma.

The chief active constituent of coffee is caffeine. This alkaloid has a definite stimulant action on the heart and blood-vessels, but in the normal adult, who takes coffee regularly, this effect is not very great if the amount drunk is moderate. Opinion is divided as to whether coffee plays any part in the production of arterio-sclerosis. Its diuretic effect is not fully explained, Dr. Irvin considers, though it may be due to dilatation of the renal arterioles coupled with cardiac stimulation. Other theories are that caffeine directly stimulates the renal epithelium or poisons the cells of the tubules, thereby preventing reabsorption, but large doses can be given to rabbits without causing damage to the epithelium of the kidney. In moderate doses coffee is said to increase alimentary peristalsis both in rate and force. On the nervous system it acts chiefly as a cerebral stimulant and this property lends itself readily to abuse which may cause insomnia and nervous irritability. As a stimulant, therefore, it should only be used in moderate strength and sober quantities. It speeds up metabolism and hastens the drain upon the reserve powers of the body, but is effective as a muscular and mental stimulant, says Dr. Irvin, only when some degree of fatigue is present. Owing to its stimulation of metabolism it is important that food should be taken at the same time when coffee is used to remove fatigue.

There appears to be general agreement that coffee should not be given to children, and Dr. Irvin, having found traces of caffeine in breast milk, suggests that it should be given very sparingly to nursing mothers.

[1] Medical Jour. and Record, Oct. 5th and 19th, and Nov. 2nd.

Sir StClair Thomson, Chevalier de la Légion d'Honneur, has been promoted to the rank of officer.

PROPOSED AMALGAMATION OF BELFAST HOSPITALS. The Board of Management of the Royal Victoria Hospital, Belfast, has decided in favour of a proposal for the amalgamation with it of the Maternity Hospital. The scheme involves a capital expenditure of £100,000, and an annual charge for maintenance of £14,000. The Maternity Hospital has 26 beds, but at least 100are needed to meet the city's requirements.

INDEX TO VOLUME II., 1927.

REFERENCES AND ABBREVIATIONS

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

VALENTINE'S MEAT-JUICE

The **Power** of **Valentine's Meat-Juice** to be **Retained,** to **Aid Digestion,** and to **Sustain** and **Strengthen** when **Other Food Fails** has been **Demonstrated** by **Hospital Physicians** and **General Practitioners.**

Pneumonia and Influenza

William H. Peters, M. D., *Admitting Physician Camp for Consumptives, State of Rhode Island, Providence, R. I.:* "VALENTINE'S MEAT-JUICE was the only nourishment retained by my five-year-old daughter during an attack of Pneumonia. She is still taking it and gaining strength. I consider that it saved her life and believe it to be the best product of its kind on the market."

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients and also personally after having been very ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. It is also very agreeable. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY
Richmond, Virginia, U. S. A.

A-12

VALENTINE'S PREPARATION
NUTRIO PER ME
VOLUME 1 4/5 OZ.
MEAT JUICE.
The result of an Original Process of preparing Meat and extracting its Juice by which the elements of nutrition are obtained in a State ready for immediate absorption.
DIRECTIONS. Dissolve one teaspoonful of the Preparation in three tablespoonfuls of cold or warm water. Boiling water changes the character of the preparation

NOW READY.

THE CONDUCT OF MEDICAL PRACTICE

By

THE EDITOR OF "THE LANCET"

and Expert Collaborators

Demy 8vo. Cloth. 348 pp.

Price 10/6 *net* (*postage 6d. extra*)

THE book, as the title says, is a guide to the conduct of medical practice. It deals with the medical career generally—with the circumstances which should influence the decision to adopt one or other of its branches, and with the various situations in which the medical practitioner is placed, both in the establishment of himself in a practice and in carrying it on with regard for his public obligations and his professional responsibilities.

The series of articles which recently appeared in THE LANCET under this same title, and signed by recognised authorities, attracted attention in a way to demand fuller treatment of the subject in a volume. These articles in whole or in part are incorporated here.

The difficulties experienced in understanding the jurisdiction and rulings of the General Medical Council will disappear upon the explanations furnished of the intentions and procedure of the Council. The full descriptions of the statutory duties of the doctor will clear up the obscurities which surround many professional questions, while definite counsel is given to meet the varying emergencies of the doctor's life.

Extracts from leading articles in contemporary journals are given on the opposite page.

THE LANCET LTD., 1, Bedford Street, London, W.C. 2

THE CONDUCT OF MEDICAL PRACTICE (contd. from opposite page)

From Leading Articles in Contemporary Journals.

BRITISH MEDICAL JOURNAL, July 30, 1927.

The author and his colleagues have certainly produced a book which cannot fail to be of service to many members of the profession and to prevent, if carefully studied, many anxieties and embarrassments.

That counsel of the order provided in this volume is needed is evident when the special position of the medical practitioner is considered. Like his fellow citizens, he has his general civic responsibilities, and comes under the legal doctrine that ignorance of the law is no excuse for a breach of the law. This burden is increased by a number of special statutes which prescribe for the practitioner duties and responsibilities in relation to the courts of justice, to various public bodies, to administrative records, and to other specific obligations, as well as to the individual patients immediately under his care. Even here, however, the list is not exhausted. In addition, there is the internal or domestic discipline of the profession as this is determined in part by the General Medical Council, in part by the rules of the various licensing bodies, and in part by established custom, order, and habit. Thus the claims are numerous and varied, and many of them are not wanting in complexity; and the opportunities for blunders and mistakes are correspondingly abundant. Mere goodwill and excellent intentions are not enough. He who would travel safely must know the risks and dangers of the road.

The book is certainly comprehensive, and indeed may be described as complete. Practical business and high doctrine are both fairly presented. Thus severe details of methodical bookkeeping and the demands of the tax collector are here, as are also the delicate questions which arise in connexion with the secrecy of professional confidences, the arrangements of partnerships, and the responsibilities due to colleagues. Chapters on the Dangerous Drugs Act and the National Insurance Act illustrate the increasing pressure of law upon medical practice; and there is no finality, for even during the present month a new Births and Deaths Registration Act has altered the practitioner's duties in certain important respects.

There are still two features of the book that particularly attract our sympathy. One is the reiterated advice to every medical man and woman to become a member of one or other of the medical defence societies. Again and again, and in spite of warnings and exhortations, practitioners are to be found entangled in perplexities and responsible for heavy legal charges when under the expert guidance open to members of a defence organisation their troubles would either never have happened or would have been easily and peacefully resolved. Members of the profession are not ungenerous to colleagues who by misadventure fall under legal and financial penalties, but appeals of this order are hard to justify when, by prudence and a small annual subscription, every practitioner can secure his own position.

A further welcome note in the book is a fairly sustained effort to show throughout that the customs and claims of medicine are founded, not on a narrow professional prejudice or selfishness, but on the broad basis of public interest. The community generally, and apparently in increasing measure, cultivates a critical attitude towards medicine and medical practitioners, and it is well that not editors alone, but the individual doctor, should be prepared to show that both the domestic rules of the profession and its external policies are framed in the interests alike of the common health and of the individual patient. The editor and his colleagues have kept this sound doctrine well in view, and for this we owe them thanks.

THE TIMES, June 23, 1927.

The Editor of THE LANCET and his collaborators have performed a public service in compiling the volume entitled "The Conduct of Medical Practice," which has just been published. The volume has been written on the assumption that the relationship of a profession to the public which it serves can never remain stationary so long as service is being given with enthusiasm. The recent swift evolution of the theory and application of medicine has produced in the minds of laymen, as well as of doctors, an attitude of expectancy which becomes easily, when hopes are deferred, an attitude of criticism, and which has expressed itself during the past few years in a series of agitations some of them well and some of them ill founded. Largely because progress has been so rapid, the idea is widely entertained that progress has not been rapid enough and that the march of progress is being delayed by outworn rules and regulations. This idea, in the view of the Editor of THE LANCET, merits the courtesy of a reasoned reply. He sees in it eagerness rather than hostility, and aims, therefore, at its utilisation as a means of furthering the cause of the public health. He has been at pains—though his book is addressed in the first instance to doctors—to discover and discuss all the relevant criticisms of medical practice and to present the answers to these criticisms in such language that anyone may understand them.

MANCHESTER GUARDIAN, July 18, 1927.

Very soon, and while still very young, he [the medical student] finds himself loose upon the world as a "doctor," more or less a public character, and a man with a bewildering number of responsibilities, statutory, legal, and social, and a very special set of "points of contact" with the society of which he has become a part. He is incidentally a man who has to earn his living. And for all this elaborate business of life he has had, as a rule, no training. There is not room for it in the university curriculum. The training of the lawyer, of the engineer, or of the accountant leads him more or less directly to his responsibilities. The medical student is practically sequestrated for five years in the dissecting-room, the laboratory, and the wards of his hospital. What he learns of the world and of his place in it is picked up in his spare moments of recreation.

The Editor of THE LANCET has filled a most important gap in compiling the present volume, of which every chapter is written by an expert on his own subject. The book should be in the hands of every "newly fledged" doctor, and as a book of reference will be found no less valuable by the most experienced.

THE LAW TIMES, July 9, 1927.

The Editor of THE LANCET and his expert collaborators are to be congratulated upon "The Conduct of Medical Practice," under which title are incorporated in whole or in part numerous articles which appeared in the columns of that publication. It is a volume that no medical man can afford to be without, for it deals in its various parts with the Medical Career, Entry into Practice, Statutory Obligations, Professional Discipline, and the Public Services. The position of the General Medical Council is clearly and accurately explained, and the portions of the book dealing with the relationship of law and medicine are exceedingly well done. In the appendix a system of bookkeeping is explained, followed by a consideration of income-tax assessment.

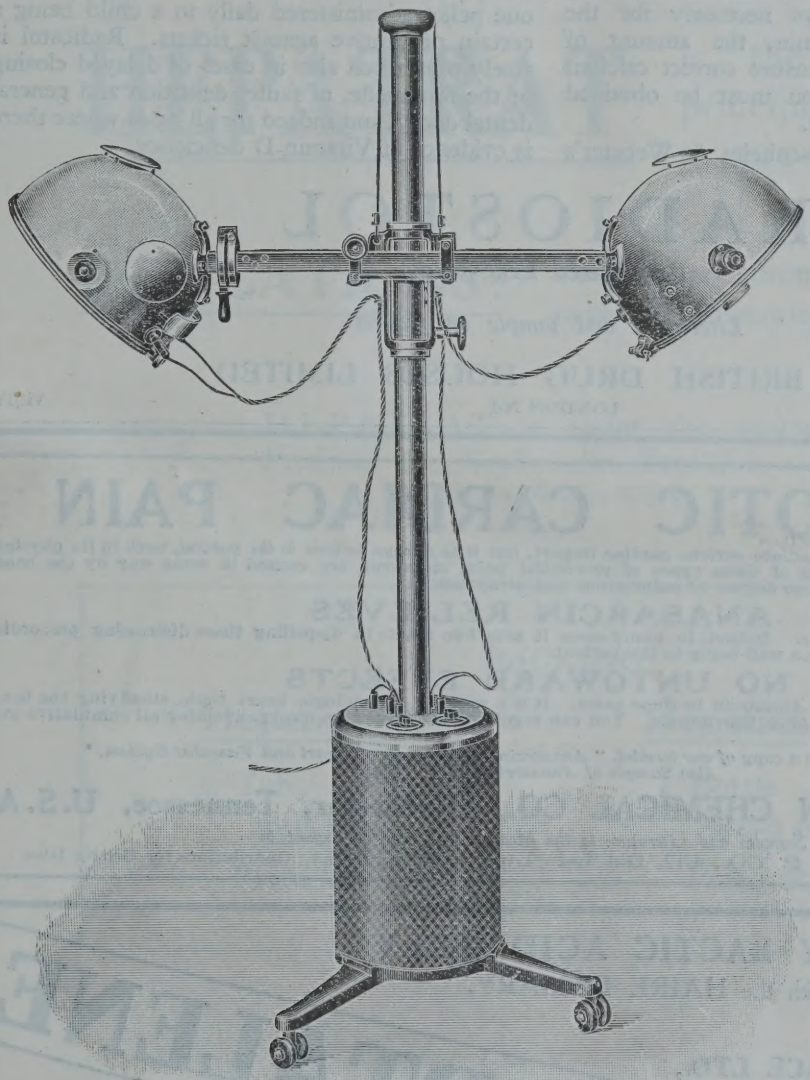
THE "TRINITY" ULTRA-VIOLET LIGHT APPARATUS

A { MERCURY VAPOUR LAMP / TUNGSTEN ARC LAMP / CARBON ARC LAMP } IN ONE

This design incorporates the valuable assistance we have received from Dr. Percy Hall, M.R.C.S. (Eng.) L.R.C.P. (Lond.), Author of "Ultra-Violet Rays in the Treatment and Cure of Disease."



The "TRINITY" Ultra-Violet Light Apparatus has been designed to meet the views of the several authorities as to which is the best type of ultra-violet radiation. There is considerable diversity of opinion as to the respective merits of the Mercury Vapour Lamp, the Tungsten Arc Lamp, and the Carbon Arc Lamp, and, as a result, intending purchasers often find it difficult to make up their minds which type to purchase. As evidence of this diversity of opinion we refer to an article appearing in the "British Medical Journal" for March 26, 1927, page 665.

The "TRINITY" Ultra-Violet Apparatus will, we think, solve the difficulty of selection, because it will be noted that at no more than the price of a single lamp we provide actually the three separate processes, which are embodied in the same apparatus, thus enabling either of the three forms of radiation to be applied at will. Hitherto this was only possible with three separate sets of equipment, entailing much greater cost and space.

Separate controls are provided, so that both lamps can be run simultaneously when desired, permitting of two or more patients being treated at the same time.

The workmanship of the whole apparatus is of the highest grade, the hoods and cross arms are carried on roller ball bearings, providing very free adjustment, while the height is variable by counterweights.

For use on Direct Current	£41 0 0
Electrolytic Rectifier for use on Alternating Current, extra	£12 12 0

Vitamin D Deficiency

A well-known authority on public health reported recently that of 1000 children all aged three years from different parts of the country, 48·7 per cent. showed manifestations of rickets. Such manifestations betray a serious Vitamin D deficiency in this country.

Vitamin D is available in nature in two ways, one by the action of sunshine on the skin, and the other through the medium of correct food. As in many countries, however, especially in winter time, food is deficient in Vitamin D and sunshine lacks the ultra-violet rays necessary for the production of this vitamin, the amount of Vitamin D necessary to ensure correct calcium and phosphorus absorption must be obtained from an extraneous source.

By the adaptation of Rosenheim & Webster's discovery that Vitamin D is produced by irradiation of ergosterol, the production of this vitamin on a manufacturing scale is now achieved in the chemical works of The British Drug Houses Limited. Irradiated ergosterol is sold under the name Radiostol, and is available at the very time when the child and adult population alike are suffering from the after-effects of a sunless summer. Radiostol is guaranteed for its Vitamin D activity by actual animal-tests.

It is issued in solution in oil and in pellet form—one pellet administered daily to a child being a certain preventive against rickets. Radiostol is freely prescribed also in cases of delayed closing of the fontanelle, of faulty dentition and general dental decay, and indeed for all cases where there is evidence of Vitamin D deficiency.

NEUROTIC CARDIAC PAIN

may or may not have an immediate serious cardiac import, but *it is always serious to the patient*, both in its physical and its mental effects. Most of these types of precordial pain, moreover, are caused in some way by the heart itself, and are attended by some degree of palpitation and arrhythmia.

ANASARCIN RELIEVES

the majority of these patients. Indeed, in many cases it acts like magic in dispelling these distressing precordial pains, and restoring comfort and well-being to the patient.

NO UNTOWARD EFFECTS

need be feared from the use of Anasarcin in these cases. It is a rational, physiologic heart tonic, steadying the beat, dilating the arterioles, and toning the muscle. You can regulate its dosage to a nicety, avoiding all cumulative and other undesirable effects.

Permit us to send you a copy of our booklet, "Anasarcin in Disorders of Heart and Vascular System."
Also Sample of Anasarcin for your trial.

INSULIN 'A.B.'

TRADE A B MARK Brand

INSULIN 'A.B.' Brand is prepared only in the form of sterile solution which is immediately ready for injection.

Its use ensures :
1. Ready adjustability and accuracy of dose ;
2. Full activity and stability ;
3. Absence of reaction and pain on injection.

'A.B.' Brand Insulin maintains a world-standard of purity and excellence ; its activity is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.

Supplied in Two Strengths :

20 units per c.c. Packed in bottles containing :
5 c.c. (100 units or 10 doses) **2/8** each
10 c.c. (200 „ 20 „) **5/4** „
25 c.c. (500 „ 50 „) **13/4** „

40 units per c.c. Packed in bottles containing :

ALOCOL

Colloidal Hydroxide of Aluminium

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralising it.

"Alocol" thus prevents reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, infective enteritis, &c.

Complete chemical history of "Alocol" with convincing clinical reports, and supply for trial, sent free to physicians on request.

Professional Endorsement

Read this Doctor's letter

London, Nov. 18, '27.

Dear Sirs,

The sample of Trufood that you kindly sent me a short time ago, I have tested on my own little son, who had to be taken off the breast for a time. The other breast milk substitutes that I tried caused great flatulence and gave him obvious pain about 1¾-2 hours after a feed, but I am pleased to say that Trufood agrees with him splendidly.

The change coincided exactly with the first feed of Trufood, and from being a fretful and tiresome baby, he recovered his usual cheerful disposition.

My observation certainly confirms the claims made for Trufood as the next best thing to breast milk, and I have no doubt that the correct proportions of Lactalbumen and Casein account for the superiority of this over other infant foods. . . .

Yours faithfully,

. . . . ., M.B., B.S.Lond.

Humanised Trufood is professionally endorsed and recommended by doctors and is invariably selected by them for their own children when breast milk fails.

This is perfectly natural since thousands of doctors in daily practice have *witnessed the normal healthy development* of infants on the food which so closely resembles Nature's own.

PROTEIN IN INFANT FOODS.

Published analyses of many baby foods can be most misleading and hide the presence of substances utterly foreign to breast milk. In nearly all these analyses Lactalbumen and Casein are grouped under the heading of Protein thus hiding their respective proportions. The medical profession will appreciate the importance of knowing the exact percentage in which these vital constituents occur. ONLY Humanised Trufood can claim the true constituents because all and no other are present—in their right proportions and condition.

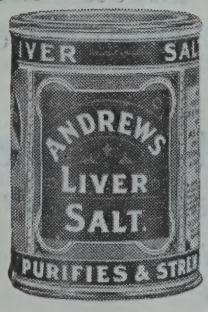
Yuletide Ills

A Merry Christmas often brings in its train the consequences of too-free indulgence in the pleasures of the table. Young and old, rich and poor alike, respond to the spirit of Christmas with light-hearted enthusiasm.

Unfortunately, Acute Dyspepsia, Biliousness, and General Torpidity are often the sequelae, and there is a physiological craving for something "sharp and fizzy."

Andrews the pleasant-tasting effervescent aperient, supplies this need. It is antacid in action and may be given with absolute safety to young children.



Dose: One-half to three teaspoonfuls, according to requirements, in a glass of water.

An 8-oz. tin will be sent free on request.

Andrews Liver Salt

SCOTT & TURNER LIMITED, Works and Laboratories at Newcastle-on-Tyne

PINHEROIN

PINHEROIN
A most palatable and effective combination which is devoid of the injurious effects of morphine, etc., at the same time it exerts a similar sedative action, lessens the frequency of respiration, but this is duly compensated by its greater depth. Its soothing effect is almost instantaneous
DOSE—One teaspoonful every two or three hours if necessary.
OPPENHEIMER, SON & CO., LTD.
179, Queen Victoria St., LONDON E.C.
BRITISH HOUSE SINCE FOUNDATION

is a cough linctus possessing many advantages over preparations for the purpose which contain Morphine. Heroin exerts a similar sedative action to that of Morphine, yet it lessens the frequency of respiration.

It is active in smaller doses than Morphine and is less depressant; does not cause constipation, and affects the respiratory more than the cerebral functions.

'Pinheroin' is palatable and soothes almost instantaneously.

Clinical Sample and Literature on request.

O. & S

Greater Germicidal Efficiency without damage to Tissues

THE efficiency of an antiseptic depends on the ratio of its germicidal power to its destructive or irritant action on living tissue. The higher this ratio, the greater the concentration in which it can be employed for any given purpose—the greater hence its efficiency.

Monsol can usefully be compared in this respect with lysol; it has been so compared experimentally by parallel qualitative and accurate quantitative tests. The results of these tests are remarkable. Monsol is, in the first place, considerably the more powerful of the two as an antiseptic. It owes this not merely to its chemical constitution, but to the fact that, unlike many coal-tar derivatives, it readily forms an exceedingly fine emulsion on admixture with water.

Virtually Non-irritant

Lysol is a highly irritant and poisonous substance. If Monsol had a similar composition, it should, in view of its greater antiseptic power, be even more irritant and more poisonous. It is *not*. It is less than one-sixth as poisonous, and so much less irritant that it can be used in dilutions which for lysol are impossible, and for purposes for which lysol cannot be used at all.

The ratio of germicidal power to tissue damage, if it could be expressed in mathematical terms, would probably be as much as *twenty times greater* for Monsol than for lysol.

Monsol has divorced these two effects to an extent hitherto unparalleled, and its therapeutic possibilities are consequently greater than those of any product of its kind.

'Byno' Hypophosphites

Trade Mark

An efficient Digestive, Tonic and Restorative

Invaluable in retarded convalescence and asthenic conditions generally.

In 'Byno' Hypophosphites are combined the tonic qualities of the Nux Vomica and Cinchona alkaloids, the restorative value of the mineral hypophosphites, and the nutritive and digestive powers of 'Bynin' Liquid Malt, which is the basis of the preparation.

'Byno' Hypophosphites has for long been prescribed with great success in convalescence after acute infections and following surgical operations; in nervous and mental conditions due to overstrain or exhaustion; as an adjunct in the treatment of tuberculosis; in asthenia of the aged, and in a diversity of conditions where a general tonic and digestive is indicated.

COMPOSITION:

Calcium Hypophosphite	2 gr.	Iron	¼ gr.	Nux Vomica Alkaloids (equal to Strychnine)	1/40 gr.
Potassium	2 „	Manganese ...	¼ „		
Sodium	2 „	Cinchona Alkaloids	1½ „	'Bynin' Liquid Malt ...	1oz.

In bottles at 3/6, 6/6, and 12/-

HYPODERMIC CASE, No. 62

Provides the physician with a portable outfit of those hypodermic medicaments most likely to be required in an emergency.

In the event of an urgent call, the Case is ready to slip into the bag or pocket, and no valuable time is wasted in finding the necessary medicaments.

Special points :—

(1) Syringe section is easily removable for sterilisation.
(2) Breakages are prevented by the spring, which reduces vibration to a minimum.
(3) When the Case is opened the 'Hypoloid' containers cannot fall out.
(4) Labels legible without removing containers from Case.

Any selection of 'HYPOLOID' products can be included in the Case, according to the physician's individual requirements.

Physicians are invited to inspect the Case at the Chief Office, Snow Hill Buildings, E.C. 1, or at the Exhibition Room, 54, Wigmore Street, W. 1. The 'Hypoloid' products required having been selected, the price can be given for the Case complete. (Physicians writing for an estimate will find a complete list in Wellcome's Medical Diary.)

THE MOST ACTIVE URIC ACID ELIMINANT

ATOQUINOL

(Allyl Phenylcinchoninester)

Atoquinol possesses pronounced analgesic, antipyretic and antiphlogistic properties. It has proved of great value when exhibited in the treatment of arthritis, gout (gastric, intestinal), neuralgia, sciatica, polyneuritis, rheumatism, etc., and it may with advantage replace the salicylates in many cases. Atoquinol is administered orally in the form of tablets (4 gr.), while Atoquinol Ointment, which is readily absorbed by the skin, may be applied locally in painful arthritis, etc.

Some Clinical Reports on the

ELIMINATION of URIC ACID by HOWARDS' AGOTAN

M.R.C.S., L.R.C.P., writes :—

"One can only theorise about the way in which Agotan and similar substances bring about the elimination of Uric Acid. That Agotan does so can be proved to demonstration and sufficiently accurately for clinical purposes by the phosphotungstic estimation of uric acid in the urine. This is accompanied by rapid mitigation of symptoms."

Capt. (R.A.M.C.) :

"In our wet and cold camp of 1926 men were continually reporting sick with sciatica or lumbago. Conditions rendered most of the accessory means of treatment most difficult but Agotan—10 grs. thrice daily—cleared the trouble up in 3 or 4 days' time despite the adverse conditions. In several cases taken at their very inception, so to speak, three doses proved sufficient."

M.B., B.Sc., D.P.H.,

Reports that he has achieved success with Agotan when salicylates, iodides, ionisation and diathermy, etc., have all been, to use his own expression, "utterly futile." "With Agotan," he writes, "one can safely prophesy an ultimate cure. Even in cases where ultimate resort had had to be made to morphine this can be discontinued in a very short time. Progress towards recovery is never interrupted by exacerbations as is so common with the majority of other drugs."

M.D. (London):

"I prefer to regard Sciatica as a neuritis and not merely a neuralgia, and I further believe that the commonest cause of neuritis is uric acid. At all events my most rapid and lasting results in its treatment have been obtained by that excellent preparation Agotan. I have had marked success with it too in that very troublesome condition Gouty Urticaria both as a curative agent and I think also as a preventive."

M.B., Ch.B. :

"The gouty subject has a notoriously sensitive stomach and an impatient disposition. Many remedies for his condition which we know to be good have to be abandoned for one or other of these two reasons. Agotan, which is a recognised eliminant of uric acid, can be used in such cases in the form of an Ointment either alone or assisted by radiant heat. This ointment should be rubbed in not merely over the area actually affected in cases of 'rheumatism' or 'gout' but for several inches all round so as to ensure absorption of a sufficiency of the drug. Both acute and chronic conditions of this kind are markedly benefited by it, and in Neuritis it is a veritable boon to all concerned."

M.D., C.M., D.P.H., etc.:

"I have run through the whole gamut of B.P. remedies, and I have tried, I think, all the proprietary uric acid solvents of the present day, but after many years of experience I have come to rely on AGOTAN as the most trustworthy preparation at present available. The conditions in which it may be prescribed with confidence embrace all forms of subacute rheumatism, muscular rheumatism or myalgia, including sciatica, brachial neuritis, and gout whether acute or chronic, and most of the gouty skin diseases. The last group often yields remarkably well to AGOTAN."

N.B.—Agotan is not a patent medicine
It is official in the B.P.C. (1923)

MUSCULAR RELAXATION

All the latest scientific investigation emphasises that complete muscular relaxation is necessary to induce sleep—it has proved that complete muscular relaxation induces the nerves to automatically relax—restful, health-giving sleep follows—insomnia and half sleep is banished.

Staples Mattress is specially constructed with these principles in view. It is so made that it yields to every curve of the figure and supports every portion of the body equally—keeping the spine and digestive organs straight, not distorted.

Spare a few minutes to investigate your patient's mattress—prescribe a Staples Mattress and your patient's body will be cradled in luxurious comfort—the weary nerves and muscles coaxed into relaxation, and the sleep the body craves will ensue.

The old-fashioned mattress sags—the digestive organs are distorted. Result: Ill-health, restlessness and bad sleep.

BY APPOINTMENT
Wire Mattress and Bedstead Manufacturers to H.M. THE KING

Staples Mattress cannot sag—digestive organs undistorted. Result: Better health, nerves soothed, better sleep.

Intestinal Disinfection

PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of Cancer.

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself. According to this writer, the toxins absorbed produce atrophic changes in the breast and other organs which are specially prone to be followed by Cancer.

There are grounds, therefore, for hoping that the use of the most efficient of all intestinal disinfectants—Kerol—for prevention and cure of alimentary toxæmia, will do much to prevent the occurrence of Cancer.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

ORAL SEPSIS.

"EUMENTHOL JUJUBES"

(HUDSON)

Made in Australia.

A Gum pastille containing the active constituents of well-known Antiseptics, Eucalyptus Polybractea (a well-rectified Oil free from aldehydes (especially valeric aldehyde), which make themselves unpleasantly noticeable in crude oils by their tendency to produce coughing), Thymus Vulg., Pinus Sylvestris, Mentha Arv., with Benzo-borate of Sodium, &c., they exhibit the antiseptic properties in a fragrant and efficient form. Non coagulant antiseptic and prophylactic, reducing sensibility of mucous membrane.

THE LANCET says:—
"In the experiments tried the Jujube proved to be as effective bactericidally as is Creosote."

Mr. W. A. DIXON, F.I.C., F.C.S.,
Public Analyst of Sydney, after making exhaustive tests, says:—
"There is no doubt but that 'Eumenthol' Jujubes have a wonderful effect in the destruction of bacteria and preventing their growth..... I have made a comparative test of 'Eumenthol' Jujubes and Creosote, and find that there is little difference in their bactericidal action."

THE PRACTITIONER says:—
"They are recommended for use in cases of oral sepsis, a condition to which much attention has been called in recent years as a source of gastric troubles and general constitutional disturbance, and are also useful in tonsillitis, pharyngitis, &c.

THE AUSTRALASIAN MEDICAL GAZETTE states:—
"Should prove of great service."

IRVING'S

YEAST-VITE TABLETS

The New Yeast Vitamin Treatment.

We hold high medical testimony showing efficacy in cases of **SEPTICÆMIA, PYÆMIA,** skin blemishes and other disorders of the blood.
They act with quick stimulating effect on the pancreas, liver and kidneys.
The antipyretic, anodyne and analgesic action is more pronounced than that of the usual coal tar derivatives, without unfavourable reaction, and have the advantage of rapid assimilation.
Of value as a vitaliser and rejuvenator.
Recommended as a nerve sedative, and of considerable value in moderating menstrual and labour pains.

We supply (without charge) to physicians, hospitals, clinics and nurses sufficient supplies for exhaustive tests.

BOVRIL in Insomnia

Writing in the "Lancet" of October 8th, 1927, a London Nerve Specialist says:—

"It is unwise to go to bed on an entirely empty stomach, since it is generally accepted by physiologists that cerebral anæmia plays some part in the mechanism of sleep. A meal tends to produce drowsiness . . . . (compare the desire of most animals to sleep following a meal)."

He goes on to recommend, *inter alia*, a cup of Bovril and biscuits half-an-hour before bedtime. Bovril provides the required sustenance in a simple, palatable and easily digestible form, thus predisposing the system to sound, healthy sleep.

BOVRIL Limited cordially invite any medical man to visit and inspect their factory at any time.
148-166, Old Street, London, E.C.1.

The Source of NOURISHMENT

VITAMIN B

Outstanding Advantages of

HOVIS

Of all kinds of bread consumed to-day Hovis is richest in Vitamin B, and, bulk for bulk, supplies the greatest amount of nourishment.

Hovis combines all the benefits of white flour with 25 per cent. of the wheat germ, the part richest in the vitamin, added.

Compared with other cereals, the Vitamin B content of milling products and yeast in 100 g. dried bread is as follows:—

White Bread	**200**
Wholemeal Bread ..	**1,450**
Hovis Bread	**2,600**

The great value of Hovis is that it contains all the elements of a complete food; it is universally liked, and containing no bran is easily absorbed.

It is also most economical, and as has been proved, the quantity necessary to furnish sufficient nourishment is small.

Were Hovis to form a part of everybody's daily diet the nation would undoubtedly be better nourished.

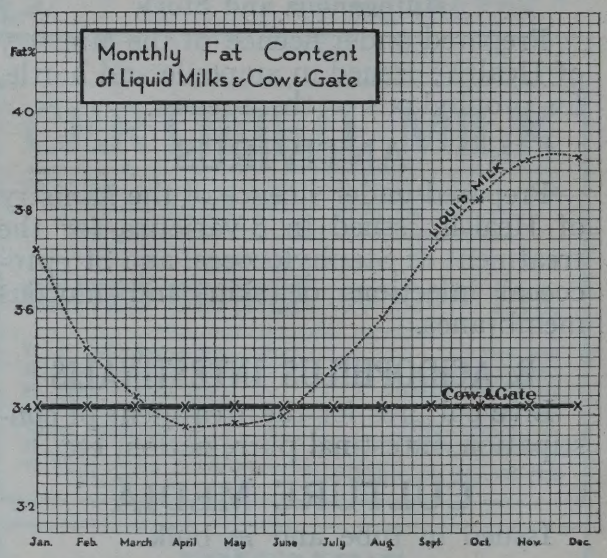
Listers

FLOUR

This flour is guaranteed strictly free from starch. It is made from especially prepared alimentary caseins and contains no gluten. It is self-rising and in individual boxes—one for each baking. A carton of thirty boxes (month's supply) £1.0.0. Makes attractive and palatable foods. Listers Flour is made only by Lister Bros., Inc., New York and Listers Limited, Huntingdon, Que., Canada. Advertised only to Physicians, whose diabetic patients may purchase it at Selfridge's, London.

A RELIABLE BASIS



The above chart shows the large fluctuations in the fat content of liquid milks throughout the year, as compared with the unvarying fat content of COW & GATE which is based on the fat content of average healthy Breast Milk.

Fat Content in . . . Cow & Gate reconstituted (1 in 8) 3·4%

Fat Content in Average Breast Milk 3·3%–3·5%

This is ONE of the many reasons why COW & GATE is the safest and most reliable alternative when breast feeding fails, and why it affords the most reliable basis for Infant Feeding Modifications.

Cow & Gate Milk Food

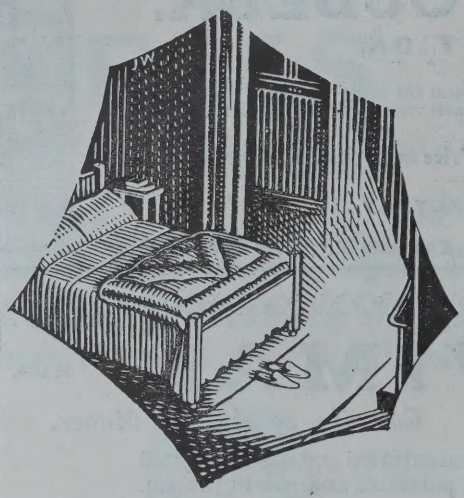
BCGA



A THIRD OF LIFE

About a third of life is spent in bedrooms—good reason to have your bedroom comfortable and warm. Yet how reluctantly and rarely are bedroom coal grates used—such trouble, oh, such labour! A gas fire on the other hand is often and gratefully lighted. Off and on at your will, without work, a gas fire in your bedroom is ideal—a godsend night and morning, a cheap insurance against chills.

GAS

The Servant of Progress

The B.C.G.A. . . . representing the British Gas Industry, is at the service of the public, without charge, for advice and help on any subject, large or small, connected with the economical and efficient use of gas in home, office or factory. A letter to the Secretary of this Association will secure prompt and careful attention.

***WHY FAIL** at the **F.R.C.S.** England (Primary or Final)?*

Enrol now for the Oral and Postal Revision Classes and make sure of success.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Exams. on several previous occasions get through without difficulty after going through our courses.
¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S. England, or both, and are highly experienced teachers.
¶ The Postal Courses are thoroughly clear, concise and up to date, and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S." free on application to the Secretary. Also Free Guide to all Medical Exams.

THE FOLLOWING COURSE OF LECTURES WILL BE GIVEN TO MEDICAL PRACTITIONERS AND MEDICAL STUDENTS UNDER THE AUSPICES OF THE

The appointment will be made in the first instance for a period of six months.

The successful candidate will be required to give certain lectures to Probationer Nurses, administer anæsthetics, carry out the dispensing and work generally under the direction of the Non-resident Medical Officer.

Applications, stating age, qualifications, and when able to enter on duties, accompanied by copies of recent testimonials, must reach me not later than Thursday, the 5th January, 1928.

WM. GEACH, Clerk to the Guardians.

5, Wellington-place, Guildford.

Derbyshire Royal Infirmary, Derby.

APPOINTMENT OF HONORARY GYNÆCOLOGIST.

The Board of Management invite applications for the office of Honorary Gynæcologist to the Infirmary.

Candidates must be qualified in accordance with the Rules of the Institution, and must undertake, if appointed, not to practise any branch of medicine or surgery other than gynæcology and obstetrics in or out of the Infirmary.

Further information may be obtained on application.

Candidates must send eighty copies of their application and testimonials (not more than three) which must be received not later than 31st January.

Any candidate who advertises in the public papers or canvasses in person or by writing will be disqualified.

By order.

WALTER BANKS, Superintendent and Secretary.

15th December, 1927.

Ministry of Pensions.

BIRMINGHAM PENSIONS HOSPITALS COMMITTEE.

HIGHBURY GROUP OF HOSPITALS, BIRMINGHAM (242 Beds).

Applications are invited for the post of JUNIOR SURGICAL OFFICER (Resident), unmarried, at the above Hospitals.

Orthopædic, General Surgical, and Medical cases are treated at these Hospitals, but the largest proportion of cases are of an Orthopædic nature.

Salary £300 per annum, with lodging, fuel, and light. The appointed candidate to be prepared to take up duty on or about February 1st, 1928.

Candidates selected for interview will be required to pay their travelling expenses.

Applications, stating age, experience, and War Service (if any), together with copies of recent testimonials, to be received not later than January 10th, 1928, addressed to the Chairman of the Committee, Highbury Hospital, Moseley, Birmingham.

Creaton Sanatorium, Northampton.

MEDICAL SUPERINTENDENT.

The Committee desire to receive applications for the post of Medical Superintendent of the above Institution which has accommodation for about 70 patients.

The salary will be at the rate of £550 per annum with furnished quarters and board, etc.

The gentleman appointed must be a registered Medical Practitioner and must devote the whole of his time to the duties required of him by the Committee. It is essential that he should have held House appointments in a General Hospital, and have had practical experience in the administration of a Tuberculosis Sanatorium, and in the treatment of Tuberculosis in such an Institution including X Ray and Ultra-violet Ray treatment, and in Bacteriological Laboratory work. He must also be specially experienced in the orthopædic treatment of non-pulmonary tuberculous cases.

The appointment will be terminable by one month's notice on either side.

Applications endorsed "Medical Superintendent," with copies of not more than three recent testimonials, must be delivered to the Secretary, 15, Guildhall-road, Northampton, on or before the 7th January, 1928.

A. CLIFFORD TOWERS, Secretary.

15, Guildhall-road, Northampton, 19th December, 1927.

Hull Royal Infirmary.—Wanted at once, SECOND HOUSE SURGEON, male, must be fully qualified and willing to hold office for not less than six months and to give and receive one month's notice to terminate engagement.

Salary at the rate of £150 per annum, with board and lodging.

Applications and testimonials to be sent to the undersigned not later than 2nd January, 1928.

BEN. BROOKS, Secretary.

Ancoats Hospital, Manchester.

HOUSE SURGEON (Orthopædic) required to commence duty on 1st February, 1928. Salary £100 per annum, with board, residence, laundry, &c. Applications, stating age, qualifications and experience, to be forwarded to the undersigned on or before 11th January, 1928, together with copies of three recent testimonials.

By order of the Board.

HERBERT J. DAFFORNE, Gen. Supt. and Secretary.

Bristol General Hospital. — The Committee invites applications from fully qualified and registered Medical Practitioners for the post of HONORARY MEDICAL REGISTRAR. The appointment will be made for twelve months and the holder will be eligible for re-election. Applications, stating age, qualifications, &c., accompanied by copies of testimonials, to be delivered to the undersigned on or before Monday, January 9th, 1928, from whom further particulars as to the duties attached to the post may be obtained.

THOMAS W. GREGG, Secretary.

Joint Nursing and Midwives' Council—

NORTHERN IRELAND.

EXAMINATION OF MIDWIVES.

The above Council being about to revise their list of Examiners, invite applications from registered Medical Practitioners, including Women, who would be willing to act. Preference will be given to applicants resident in Northern Ireland. Particulars on application to the Registrar, 118, Great Victoria-street, Belfast, to whom applications should be sent not later than 16th January, 1928.

The Lawn, Lincoln.

REGISTERED HOSPITAL FOR MENTAL PATIENTS.

The Governors invite applications for the post of MEDICAL SUPERINTENDENT (male or female) of the above Hospital.

Salary £700 per annum, with full board and house (part furnished).—Applications, stating age, previous experience, with copies of testimonials, to be sent to the Secretary, The Lawn, Lincoln, on or before 13th January.

Royal Aberdeen Hospital for Sick CHILDREN.

Applications are invited for the post of LADY SUPERINTENDENT of the Hospital—80 beds. A New Hospital of 132 beds is in course of erection, and will be ready for occupation in the course of 1928. Particulars will be supplied by Mr. A. S. R. Bruce, Advocate, 12, Dee-street, Aberdeen, with whom applications, along with twenty-four copies of testimonials, must be lodged by 10th January, 1928.

Aberdeen, December, 1927.

Shanghai Municipal Council.

PUBLIC HEALTH DEPARTMENT.

ASSISTANT PATHOLOGIST.

An Assistant Pathologist is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than thirty years of age, and must hold qualifications in Medicine and Surgery of University Standard, a D.P.H. and D.T.M. & H., though not essential, are desirable.

Salary Taels 600 per mensem, under three years' agreement, renewable at a higher salary in the event of satisfactory services. First-class passage is given, with half-pay during voyage.

Eight months' leave is given on full pay, with first-class passage, after every period of five years' service in Shanghai.

Free medical attendance is provided, and there is participation in the benefit of a Superannuation Fund.

A tael at the present rate of exchange equals 2*s.* 6*d.* Exchange is, however, subject to fluctuation.

Particulars of the appointment and full details as to the benefits enjoyed by Municipal employees under their terms of service, and as to cost of living, &c., may be obtained from the Council's Agents.

Applications, in candidates' own handwriting, with full information as to qualifications and experience, &c., accompanied by at least three recent testimonials and endorsed "Assistant Pathologist" on the cover, should be forwarded to

JOHN POOK & COMPANY,
Agents for the Municipal Council of Shanghai,
68, Fenchurch-street, London, E.C. 3.

January, 1928.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880)

Tele Address: Triform, Wesdo—London. **12, Stratford Place, Oxford Street, W.1.** Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the British Medical Association has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

MEMBERS OF THE BRITISH MEDICAL ASSOCIATION MAY TAKE ADVANTAGE OF A REDUCED SCALE OF CHARGES APPLICABLE TO THEM.

For the sake of reference the business undertaken by the BRITISH MEDICAL BUREAU is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the BRITISH MEDICAL BUREAU. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the BRITISH MEDICAL BUREAU to ensure that only the most TRUSTWORTHY AND RELIABLE Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the BRITISH MEDICAL BUREAU. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The BRITISH MEDICAL BUREAU has its own staff of fully qualified Accountants wholly engaged on Medical work, i.e., Investigation of Practices for purchasers, Income Tax, Auditing books and accounts, etc.

SCHOLASTIC DEPARTMENT.

Medical Men will find this Department of the BRITISH MEDICAL BUREAU of great assistance in the selection of Educational Establishments, Private Tutors, Governesses, etc. Prospectuses and advice gratis.

All correspondence and applications should be addressed to **A. V. STOREY, General Manager.**

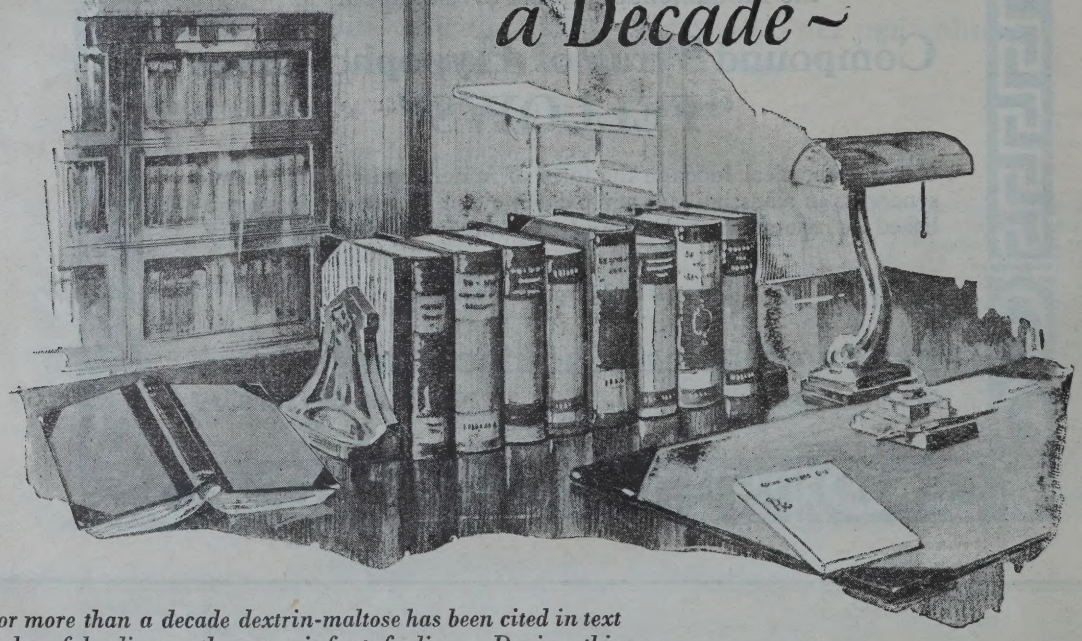
THE SUGAR FOR INFANT DIETS

Cited in Text Books of Over a Decade~



For more than a decade dextrin-maltose has been cited in text books of leading authors on infant feeding. During this period no reversal of opinion has occurred, and the opinions set out by the earlier writers are shared by those of to-day.

MEAD'S DEXTRI-MALTOSE

Samples and Literature on Request

"*Tolerance*"

"Infants will tolerate a much higher mixture of maltose and dextrin than either lactose or cane-sugar."

"*Digestibility*"

"Malt sugar (dextrin and maltose) seems to be more easily digested and better taken care of by infants having had much digestive trouble."

"*Weight*"

"Maltose and dextrin compounds can frequently be added to the diet to advantage in the presence of stationary weight because they can be added to the mixtures in quantities approximating one-eighth of an ounce (four grams) for every pound normal weight when indicated."

THE MEAD POLICY

There are no feeding directions on the tins of MEAD'S DEXTRI-MALTOSE, thus leaving the feeding strictly under professional supervision. Literature supplied only to doctors, hospitals and clinics
